PREFACE TO THE SERIES

THERE are two reasons why I have written these books: first, in response to thousands of my pupils throughout this country and Canada who desire the instruction in a more tangible form than simply through the medium of the voice; second, that the general public may have the result of thorough, honest, and unbiassed investigation extending throughout a period of thirty-five years

Having kept abreast of the times, I am fully aware of the conclusions other writers have reached, especially on spiritism; and am further conscious of the fact that, with few exceptions, I do not, in the main, agree with these. However, my decisions have in no way been influenced by any writer, not even by my friend, the late Dr. Thomson Jay Hudson, whom I first met in 1899. When our paths converged, we found we had been

FEB 19 '37 Mrs. W. C. Headen
997538

travelling on parallel lines for twenty-five years. Comparing notes, I was pleased to learn that we had arrived, practically, at the same conclusions; therefore, there may appear to be much of Hudson in my writings, and it could not well be otherwise, especially on spiritism. I felt highly honored to have so great an authority bear so corroborative testimony.

By consulting the topics treated it will be observed that I have covered a much wider field than those who have preceded me, having touched upon every phase of Psychic Phenomena. This I have done as briefly and concisely as possible and practicable, and while my decisions are positive, they are neither arrogant nor dogmatic.

E. B. W.

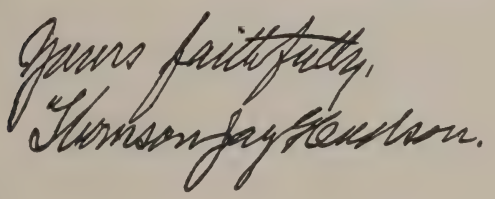
Los Angeles, Cal.
August 1, 1910.

THE following letter, which speaks for itself, is from the late Dr. Thomson Jay Hudson, the author of "The Law of Psychic Phenomena," etc.:

No. 10 Ninth St., S. E.,
Washington, D. C., May 2, 1900.

I consider Mr. Edward B. Warman the peer of any man in his line; in fact, I know of no one who covers so wide a field. His experiences in Mental Telegraphy are equal to any I have ever known; he is the most practical psychologist it has ever been my pleasure to meet; his explanation of Hypnotism removes all fear; his sifting of the grains of truth from the Christian Science doctrine leaves nothing to be desired; his exegesis of Spiritism is scientific and logical, acknowledging, as every thorough investigator must, the alleged phenomena, but denying, as every logician must, the alleged cause. His Suggestions to Mothers are simply invaluable.

I heartily commend him for his sound doctrines.



"Words are things, and a small drop of ink
Falling, like dew, upon a thought, produces
That which makes thousands, perhaps millions,
think."

INTRODUCTORY

THE following pages have been devoted to the Law of Suggestion, not only as a healing art but as regards its effect upon various phases of life.

Suggestive therapeutics is no longer in the experimental stage but has become an established fact. The Law of Suggestion correlates all systems of mental healing; and all healing by mental processes is dependent upon the law of suggestion consciously or unconsciously applied.

Reputations are ruined, hearts are broken, homes are blighted, health destroyed, ofttimes, by one little word, look, or act, which, in itself, may have been only suggestive. On the other hand, by the same law of suggestion, reputations have been saved, hearts made lighter, homes made brighter, and health restored.

Not only are we governed in a greater or lesser degree by the suggestions of others, but in a marked degree by our auto-suggestions. It behooves us, then, to understand the workings of that law.

E. B. W.

SUGGESTION

FAITH AN ESSENTIAL ELEMENT — PSYCHOTHERAPY — THE CHRIST HEALING — THOUGHT, AN ORIGIN OF DISEASE — ADVERSE SUGGESTIONS — CAST OUT FEAR — FEAR AND DEATH — SUGGESTIVE THERAPEUTICS — POWER OF THOUGHT IN AUTOSUGGESTION — IMAGINATION AND SUGGESTION — IMAGINATION EXTRAORDINARY — CHANGE OF CLIMATE DID IT — SUGGESTIONS TO AND FOR MOTHERS — FOR CHILDREN BACKWARD IN STUDIES — SUGGESTION AS AN EDUCATOR — WHY REPEAT SUGGESTIONS — CAUTIONS TO MOTHERS — SUGGESTIONS TO THE DYING — METHOD FOR ABSENT TREATMENT — A REMARKABLE CASE OF SUGGESTION — A FEW EXPERIENCES IN HEALING.

FROM the dawn of creation to the present moment there has been no greater curative agency known to man than Suggestion; and at no time in the history of this nation has its power been so generally recognized as at the present.

The Emmanuel Church Movement, of which much has been written, is antedated by *the* Emmanuel Move-

ment which had its initiative in the teachings and practices of the lowly Nazarene; but it has taken the churches nearly two thousand years to recognize the fact that man has a body as well as a soul; to come to a realizing sense that somehow, somewhere, the teachings and practices of the healing art have been lost to the Church, while, in reality, the power exists to-day as it did in the days of Christ.

FAITH AN ESSENTIAL ELEMENT

Whether you are projecting your thought to help another, or giving suggestions to yourself (autosuggestions), faith is absolutely essential — faith on your part, faith on the part of the recipient.

Mental healing or mental aid of any kind depends upon mental attitude and conditions. As has been so well said by the late Dr. Hudson —

"Jesus of Nazareth was the first to define the condition necessary to successful mental healing. His whole career was demonstrative of the truth of His declaration. All the experimental researches of nineteen supervenient

centuries have served to confirm and illustrate its truth. In that declaration He summed up the whole law of mental healing in that one word 'Faith.' That was the one mental condition on the part of the patient which He constantly insisted upon as essential to the exercise of His power. That it was essential was clearly evidenced by the fact that He could not succeed in healing the sick in His native city 'because of their unbelief.'

"Mental healing is not due to some agency extraneous to the patient himself. The words of Jesus emphatically negative the belief in any extraneous agency whatever. The word 'faith,' as before remarked, indicated the mental condition essential to success in healing. It is the energizing principle of the human soul, and without which it is powerless to heal the body. And when Jesus declared to his patients as He did with insistent iteration 'Thy faith has made thee whole,' it was a clear, positive, and emphatic statement of the one basic principle of suggestive therapeutics. It was equivalent to saying, nineteen hundred years in advance, just what modern experimental science has demonstrated to be true, namely, that the mental energy that heals the sick resides within the patient himself. All that the healer does or can do — all that Jesus did or pretended to do — was to induce in the mind of the patient the necessary mental condition to stimulate by appropriate acts and words the energizing principle of his soul — faith. No act or word of Jesus militates in the slightest degree against that one emphatic declaration. It was, in fact, a proclamation,

or formulation of the Supreme Law of Suggestive Therapeutics — the law under which he performed His wonderful works; the law that He taught to His disciples; the law under which His promise was made that those coming after Him should do 'even more wonderful works' than He had done; the one universal law under which all mental healing has been accomplished since the beginning of time."

The power of Suggestion is manifest in every instance of Christ's healing. I also think it is very evident that Christ worked in full accord with natural laws; in fact there is nothing supernatural. That which is called supernatural is merely superusual or supernormal. The word *supernatural* is a contradiction. Everything in the universe is, in a sense, natural. The so-called supernatural is the natural not yet understood. It is often but the figment of a disordered, undisciplined, or undeveloped imagination.

The disciples worked upon the same basis as did Jesus. The only difference, evidently, between the Master and His disciples was in the larger recognition of a force (energy) which was possessed by both; an en-

ergy that was active in the one, latent in the other.

PSYCHOTHERAPY

Psychotherapy — the healing art practised by Christ and His disciples — differed from that of the more modern movement in this regard. He knew no limitations, but "He healed all manner of people." He, knowing full well that a physician's diagnosis is not infallible nor his judgment faultless, did not ask for a physician's certificate. All that was required, regardless of the nature of the disease, was, as has been said, faith, implicit faith in the inherent power. The gist of the whole matter lies in the law of suggestion which sets in motion the dynamic force of thought.

"Because the works of Christ were apparently a deviation from the known laws of nature," said Dr. Hudson, "is no evidence whatever that they were beyond the pale of the law. Christ understood every impulse of the human soul. There was no

phase of character that He did not read at a glance."

In the case of the man born blind I do not, for a moment, believe that any learned theologian would contend there was any efficacy in the ointment made of the clay and the spittle, nor in the water of the pool of Siloam in which he was told to wash. These were powerful conductors of suggestive force and psychological power.

There are thousands of cases on record from the time of Christ to the present day that give indisputable evidence that psychotherapy will absolutely cure that which medicine cannot even faze. Take, for instance, the Biblical record of the woman who "pressed through the throng and but touched the hem of His garment and was instantly cured after having suffered many things of many physicians for twelve years, and had spent all she had and was nothing better but rather grew worse." (This is the record given by Mark, but Luke, being a physician, gives a different account and thereby avoids the reflection on the medical profession.)

Same old story repeated over and over again in this our day — "spent all she had, was nothing better but rather grew worse."

I believe in giving due credit to the medical profession for the progress it has made, and feel assured that the day is not far distant when it will progress to such an extent that drug medication will be a thing of the past and that its place will be filled, largely, by psychotherapy, for it must be admitted that no doctor knows with any degree of certainty the action of the drug or poison he administers. He simply prescribes as he was taught or as subsequent observation and experience dictate, and then awaits the effect. In the meantime the patient can thank his strong constitution for having survived the treatment.

Leading men in the medical profession are rapidly coming to the front and acknowledging the power of suggestion in psychotherapy. Dr. Frederick Van Eeden of Holland, the Dutch author, poet, and physician, widely known in this country, declares that he has given up the prac-

tice of medicine because the so-called science is rapidly becoming obsolete. To a large audience in New York City he said: "I gave up the practice of medicine years ago for the more effective treatment of suggestion. Many doctors who are practising medicine to-day rely more on suggestion than they do on drugs, but they do not like to admit it. When doctors of medicine cannot diagnose a case or do not know what to do for a patient they give him a placebo with careful instructions as to the manner of taking. Usually they tell him it is a most powerful drug. This is an admission that even in extreme cases physicians advocate suggestive therapeutics. A famous London physician told me that when he felt ill he used to take two rhubarb pills and put them on the table by the side of the bed when he retired. He declared that the effect was just the same as if he had taken them. This is but an example of what suggestion will do for the body."

It is usually claimed by orthodox medical men that psychotherapy does not avail in other than functional dis-

orders; therefore is not to be commended in organic diseases. This is where the Emmanuel Church workers were and are handicapped. On this subject I quote Dr. Sheldon Leavitt of Chicago.

"After a medical and surgical practice of more than twenty-five years, I affirm that ordinary methods cannot cure as many cases of organic disease as can psychotherapy, and that they are wholly unable to cope with nervous disorders by the strict use of customary remedies. Approved psychotherapy makes as free and intelligent use of ordinary hygienic measures as does medicine; they are common property."

Even Dr. Hugo Münsterberg, the Harvard psychologist and neuropathist, says: "We recognize that every so-called functional disease has its organic basis, also."

The doctor's knowledge of the human system is not to be underrated; it is, in fact, of inestimable value; but psychotherapy, the healing ministry of Christ, can be restored without injury to either the medical profession

or intelligent Christianity, and without detachment from either the doctor or the Church. While it is true that we have no right to withhold the curative medicine that poisons the protoplasm of the offending bacillus, antagonizes pathological conditions, arrests exaggerated tissue waste, or upbuilds impoverished cells; yet, that curative agency is not necessarily drugs.

I would not be understood as having any antipathy toward doctors; many of them are among my most intimate and valued friends. I think, as professional men, they are the most self-sacrificing on the face of the earth. Patient? Yes. "Patience on a monument," notwithstanding the fact that many of their patients are put *under* a monument. Cheerful? Yes, as they should be under the most trying circumstances; for instance, a lady patient said to her family doctor, "Oh, doctor, I shall never get relief until I am in my grave." Said the cheerful doctor: "All right, don't worry, I 'm doing what I can for you."

THE CHRIST HEALING

Elizabeth Stuart Phelps Ward said:

"Christ was an 'irregular.' He defied all the prejudices and tyrannies of the old, established schools. He treated one who was ill not in the way that was agreeable or pleasing to the medical profession but in the way that was best for the patient. He realized that they suffered more from the abuses of the profession than from the effects of the disease. He discarded all drugs and nostrums, all the nauseating superstitions of His age, and lifted His patients to a plane of pure living and high thinking. He paid no attention to popular opinion if He believed that opinion to be wrong.

"The healing gift of the Nazarene was a force which the world had never met before. Its simplicity, its good sense, its astounding results overthrew the therapeutics of His time. The sick public went over *en masse* to the singular healer whose prescriptions demanded of His patients only two things — respect for themselves and faith in Him.

"The personal vitality of Jesus proved itself equal to every claim that He made so long as He lived and healed. No soul has ever visited this earth who so understood the piteous fate of physical misery which curses it. To this one kind of suffering He was superlatively responsive. He never forgot, never neglected, never failed. He never overlooked, never slighted, never showed a weak hour nor a cold

imagination. He was always sorry, always tender, always strong.

"Jesus, the healer, had no specialty. He took all kinds of cases. It is not known that he ever failed. His practice appears to have extended over every variety of disease known to His disordered land. Out of the thirty-six so-called miracles, twenty-four of them were those of healing."

It may truly be said of Jesus of Nazareth that He was too human to be all divine; too divine to be all human. We may call Him man, or call Him God, or call Him God-in-Man, or man-from-God, the title is less important than the fact.

THOUGHT; AN ORIGIN OF DISEASE

Dr. Chas. Gilbert Davis, of Chicago, in his "Philosophy of Life," speaks in no uncertain tones on this subject:

"If a thought can in an instant of time dilate or contract the blood vessels, causing a rush of blood to or from any part; if it can increase or diminish the secretion of a gland; if it can hasten or retard the action of the heart; if it can turn the hair gray in a single night; if it can force tears from the eyes; if it can in an instant produce great bodily weakness; if it can produce insomnia; if, as has often occurred, it can bring instantaneous death — then is it not

natural for us to conclude, without further argument, that it may bring about a more or less continuous derangement of the physical organism, which we call disease?

"On every hand we note instances where the action of the mind both produces and perpetuates disease. Indeed, I can truthfully say, after an observation of many years in the practice of medicine, that a majority of the cases of illness which come under the daily observation of the physician are largely due to the condition of the mind.

"It is not unusual for some one returning from the funeral of a loved one to be taken ill and in a few days follow that one to the grave. What causes this death? Depressing thought. A mother hears of some calamity having befallen her child. She goes into a collapse, fever follows, and she is near the gates of death. Was it not a thought that produced this illness? A man is seated at a banquet table, full of health and happiness and blessed with a good appetite. A message is brought to him that his family has been drowned in a flood. He turns pale, his appetite deserts him, and his strength is gone, Soon he is in a delirium and ill. All the functions of the body are deranged; a doctor is called and names his disease. But is it not true that this man's disease has been produced by what he thought?

"I have seen the most wonderful effects follow a fit of anger. After an outburst of passion the function of every gland in the body is impaired. Time and again I have observed acute illness in an infant where it was permitted to nurse immediately after the mother had been

engaged in a quarrel, and on more than one such occasion I have seen death follow in a few hours.

"Such instances might be multiplied indefinitely, and every observant physician has a mental store of such cases.

"The standing army of the human body is the corpuscles of the blood—the red and the white. Upon these we depend to heal the wounds, build up new tissue, and attack the poisonous bacilli that may attempt to enter the system. Upon the healthful condition and number of these little soldiers depend our lives. Let their vitality or number be reduced and the invading bacilli scale the ramparts, swarm over the body, and, taking possession, destroy it.

"Thought produces disease or health because of its action on the corpuscles of the blood. These corpuscles are wonderfully influenced by the mind. An outraged conscience, hate, envy, anger, and fear crush the vitality out of them and leave the citadel of life exposed. But faith, hope, happiness, and love create them and send them swarming through the body till every fibre and tissue throbs with life. This is demonstrated by the microscope.

"Examine the blood of a man or woman living a life that constantly outrages a previously finely educated conscience, and you will find the corpuscular element far below par. Examine the blood of the fallen woman who has been reared and educated in the strict tenets of the Church, but who has drifted away into the haunts of sin, with a conscience night and day goading her to the brink of despair, and I defy you to tell me her blood is healthy."

This is not mere theory with Dr. Davis. A few years ago, by means of trained nurses and assistants, he conducted a series of scientific experiments. In this connection he sent his assistants into the haunts of the vicious and the homes of the righteous.

Thus it may be seen that disease may be created and maintained by what we think, and disease may be averted, notwithstanding the presence of dangerous bacilli in the body. Hence the value of psychotherapy as a curative agency.

ADVERSE SUGGESTIONS

When you *have* been healed, whether by yourself or by another (I should say, through the aid of another), you should heed the injunction so wisely given — "See thou tell no man." No recorded words that the Master ever uttered display a more profound knowledge of the underlying principles of mental healing than do these. One should always be on his guard to fortify himself against the adverse suggestions that come

from the ever-present sceptic. The world is full of doubting Thomases. It is well to keep your own counsel in the presence of such men.

In all self-help, in healing or in business, concentrate your mind with implicit faith on that which you desire rather than upon the condition that exists, if the condition that exists is not desirable. Mind being indivisible, you cannot hold it upon a diseased condition of the body and at the same time expect health. You cannot dwell upon failure in business and at the same time expect success. Remember they *can* who *think* they can.

Also bear in mind that the words *hope* and *expect* are not in reality synonymous. There are many who *hope* to receive, *desire* to receive, yet do not really *expect* to receive. True expectancy always implies faith; but not the faith that the woman used on the ash heap. As she was locking the rear door of her house she saw the mound of ashes in the back yard. She said, "I am told that if you have faith, even as a grain of mustard seed, you can remove a mountain. Well, I don't

believe it, but I'm willing to try it on the ash heap." In the morning when she opened the rear door, seeing the ash heap still there, she exclaimed, "Just as I expected."

The world to-day is full of illustrations of the efficacy of suggestion through *faith*. The physician who can arouse it and carry it along the lines of known scientific truth is capable of reaching the highest pinnacle of professional usefulness in the age in which he lives.

CAST OUT FEAR

The element of faith dispels every particle of fear. No disease can be cured by any means whatsoever until all fear is eliminated. Fear is negative. Fear invites, albeit in a negative manner. You may remember the fate of poor old Job — "The thing which I greatly feared is come upon me." Fear lessens the vital action, obstructs the functions of the glands, retards the secretion of the gastric juice, diminishes the vitality of the red and white corpuscles — the standing army of the body,—and so the invading host en-

ters and takes possession and destroys the life. This is well expressed by R. R. Bowker, in the little poem—

FEAR AND DEATH

"The Spirit of the Plague entered the gate.
One watching asked, 'How many wilt thou slay?'
'One thousand,' spake the Spirit, 'is my quest.'

"The Plague made end. The Spirit left the gate.
The watcher cried, 'Ten thousand didst thou slay!'
'Nay, one,' the Spirit said; 'Fear killed the rest.'"

I would encourage you to treat fear as an enemy, that is, face it. Many years ago (1876) Kit Carson, Jr., impressed me very strongly with the physical element of courage, and in an interview with him I asked him to favor me with a written sentiment in addition to his autograph. On the back of a card he wrote, "True to friends and square with enemies." To this he signed his name. That sentiment was to me a very strong suggestion to be applied mentally and morally as well as physically. You

cannot be square with any enemy unless you have courage, and courage never turns her back.

"Flee from fear, and still the faster
Fear comes on.
Turn, assert yourself the master;
Fear is gone."

SUGGESTIVE THERAPEUTICS

The mind is always controllable by suggestion. A suggestion, however, is not necessarily verbal, but is something you can see, smell, hear, touch, or taste. The mind can be stuffed, starved, or poisoned as truly as the body. I have every reason to believe that there is not a disease known to man which cannot be remedied if the mind of the patient be prevented from retarding the recovery of health. Friends and sympathetic relatives also have, unintentionally of course, killed many persons by misdirected kindness and overanxiety.

Suggestive therapeutics is an established fact. It is rapidly taking its place as a remedial agent. Wherever we go, and in every case of sickness,

we witness the power of suggestion. Suggestive therapeutics, however, is not infallible, says Bernheim, although it gives good results in a very large number of cases. It may fail even when it is intelligently and persistently managed. The cause of the failure is inherent; sometimes in the disease, sometimes in the subject. One who uses suggestion never has need to deny the existence of disease, but he should assert positively and truthfully that the disease is amenable to cure, and that recovery will follow as the result of the treatment.

That there is inherent in all mankind a psychic power presiding over the functions, conditions, and sensations of the body, and that the power can be evoked and controlled at will under proper conditions, is no longer a matter of doubt to reasonable investigators. This inherent power, known as the subjective mind, runs the entire human machinery when the objective mind is either asleep or in abeyance; in fact, it runs the machinery of life all the time, but it runs better when not interfered with by adverse suggestions from the objective mind. It has

absolute control over all the functions —nutrition, waste, all secretions and excretions, the action of the heart in the circulation of the blood, the lungs in respiration, and over all cell life, cell changes, and development.

"I do not pretend," says Bernheim, "that suggestion acts directly upon the diseased organ. Diseases are cured, when they can be cured, by their natural biological evolution. Ordinary therapeutic methods consist in putting the organism in a condition such that the *restitutio in integrum* may take place. We suppress the pain, we modify functions, we let the organ rest, we calm the fever, we retard the pulse, we induce sleep, we encourage secretion and excretion; and, acting thus, we permit nature (the healer), or, to speak in modern language, we permit the activity of the forces and the properties inherent in the biological elements, to accomplish their work."

Every element of the organism has, so to speak, its centre of action bordering upon the brain. Sensibility, movement, nutrition, secretion, excretion, and calorification are governed,

or at least influenced, by this central organism which presides over the complex mechanism of animal physiology.

Suggestion is of special value to physicians. I think Dr. Parkyn is quite right in declaring that "physicians study the anatomy and physiology of the brain, but they sadly neglect the study of its functions." The chief and greatest function of the brain is to receive, associate, and store away all impressions received through the senses, and to reproduce these impressions when necessary. Through the mind every organ of the body may be assisted, and it is through unconscious action of the mind upon the body that so many diseases are produced and so many cured.

A study of psychology and suggestion will enable a physician, when a patient first consults him, to ascertain the part imagination plays in the complaint. Imaginary or not, it is real to the patient. Every careful observer knows that the functions of the human body may be greatly disturbed, as noted by Dr. Davis, through mental influences, and that such disturbances,

if prolonged, result in fixed functional or nervous diseases, and that these functional derangements often terminate in organic disease and sometimes in death.

That mental activities are capable of producing chemical and anatomical changes in our bodies is a demonstrable fact. It is also true that, while properly directed thoughts are always conducive to conditions of health, perverted mental conditions as certainly produce functional and organic disease.

Alcoholism is now justly regarded as a perverted mental condition, of which the uncontrollable drink habit is the outward manifestation. The fact that alcoholism yields so readily to suggestive therapeutics is proof positive of its mental origin, and on this account its rational treatment can be accomplished only along the line of psychic methods.

"The Law of Suggestion," says Dr. Hudson, "correlates all systems of mental healing; and all healing by mental processes is dependent upon the law of suggestion, consciously or unconsciously applied."

A *placebo* is a therapeutic suggestion which the *medical* profession has thoroughly understood and successfully practised for centuries.

An *amulet* is a therapeutic suggestion which the *superstitious* have effectively employed for ages.

Saintly relics are therapeutic suggestions which "*the Church*" has employed with wonderful success since the days of Constantine.

The *insensate* jargon of the "*Christian Scientist*" constitutes a therapeutic suggestion which has proved effective in thousands of cases. It is especially efficacious with those who are governed by their emotions and are untrained to habits of correct reasoning.

It will thus be seen, *first,* that an effective suggestion is not necessarily an *oral* suggestion; *second,* that it is not necessarily a statement of fact; *third,* that the power that effects the healing is resident within the patient himself, and is not dependent upon any extraneous force whatsoever.

Thus it will be seen that a therapeutic suggestion may be absolutely false, considered as a statement of fact, and

yet be therapeutically effective. Were it not true, a *placebo* could never have been effective. Were it not true, Christian Science would never have had an existence.

POWER OF THOUGHT IN AUTO-SUGGESTION

Autosuggestion (self-suggestion) is as potent in its influence as suggestion by another. Even when reason is dethroned, the thought held by the subjective mind (the mind of the soul) having become the dominant idea, holds the power over the bodily functions. The following convincing illustration is vouched for by the *Lancet,* London, England:

"An English lady, disappointed in love in her younger years, became insane and lost all account of time. Believing she was still young and living in the same hour in which she was parted from her lover, taking no note of years, she stood daily before the window watching for his coming. In this mental condition she remained young.

"Some American travellers who saw her were asked to guess her age. They, unacquainted with her history, placed her age under twenty. She was at the time seventy-four, but she had not a wrinkle or gray hair;

youth sat gently on cheek and brow. She was held by the thought of youth and love, and it retarded the marks of age."

Many persons have recently been cured at Lourdes, France; thousands have left their crutches at the shrine of saints and gone away rejoicing; multitudes have touched what they supposed to be a piece of the true cross, and were healed. The healing power was not in the inanimate objects, nor was there anything miraculous in the cures; in each case it was simply the result of autosuggestion, the belief in the curative powers of the things seen or touched.

IMAGINATION AND SUGGESTION

The imagination may be wrought upon by reading, as instanced by patent medicine advertisements, or by hearsay, or may be wholly creative. In each case it is the outgrowth of a mental condition; and the result is that the unreal becomes real, the ultimate result frequently proving fatal.

The fatal power of imagination was illustrated recently in the case of a Russian railway employee who was

by accident shut up in a refrigerator car.

He wrote on the wall, "I am becoming colder." Later, "I am slowly freezing." Still later, and the last, "I am half asleep; these may be my last words."

When they took him out he was dead; but it was found that the temperature of the car was 56 degrees. The apparatus was out of order. His autosuggestion, working on his imagination, killed him.

It does not always prove fatal but sometimes amusing, as in the case of the elderly couple spending their first night in a Pullman sleeper. Shortly after retiring, the following conversation took place:

Wife: "You must raise the window or I'll smother; it's very close and stuffy in here."

Husband: "If I raise the window I'll catch my death of cold."

Wife: "Well, I'll smother, I know I will, I can scarcely get my breath."

Husband: "All right, I'll raise it for your sake, no matter what may be the consequences to me."

As soon as the window was raised

the husband began sneezing, while the wife, taking a deep breath, exclaimed, "My! how refreshing."

Imagine their surprise when in the morning they discovered that it was a double window and only the inner one had been raised. The husband caught cold and the wife was refreshed by the same current of air — which existed only in their imagination.

IMAGINATION EXTRAORDINARY

The Philadelphia Press gives the following interesting and highly suggestive incident of the power of suggestion through imagination:

"On one occasion when Li Hung Chang, as premier, was having a bitter fight with some of the more conservative members of the Tsung Li Yamen, he received as a present a magnificent cake which he had reason to suspect contained poison. He put the cake aside and set to work to find out who was at the bottom of the plot. The crime was traced to three men, one of whom, at least, was absolutely guilty. Li had the trio brought to the yamen. When they arrived they were ushered into his presence and were received in his courtliest manner. The cake was produced with the remark that 'politeness forbids my tasting it until the three

generous donors have had an opportunity to enjoy its excellence.'

"Li cut the cake, and one of his servitors handed it to the unwilling guests. Each took a piece and ate, or pretended to eat. One of them crumbled the pieces and let them fall upon the floor, but the two others ate calmly without manifesting any emotion.

"Within ten minutes the two men began to show symptoms of suffering. Li smiled benignantly and said to the man who had not eaten: 'Your wisdom is so great that I am compelled to preserve your head as a souvenir of transcendent genius.'

"The man was removed and promptly decapitated. To the two others the premier remarked: 'The cake you ate is not the one you sent, but one which I had my cook imitate. The poison from which you are suffering exists only in your imagination. I know of no better way to cure your present pain than by letting you share the same fate as your friend who has just left the room.'

"As they were led away, Li said to his retinue: 'It is a pity that men who can eat a deadly corrosive poison with an unmoved countenance should so misapply the talent wherewith Heaven has endowed them.'"

CHANGE OF CLIMATE DID IT

Some time ago the Virginia State line was changed so as to include a patch of territory heretofore belonging to North Carolina. A section of

the land thus transferred included a tumble-down cabin, where dwelt an aged negro woman. An inquisitive neighbor, calling to see how the negress enjoyed the idea of becoming a Virginian in her old age, began by asking:

"How 's the rheumatism, auntie?"

"Bettah, praise de Lawd."

"And the neuralgia?"

"Done gone. Clean depahted."

"And the stiff knee?"

"Frisky as a li'l colt."

"Why, auntie, how on earth do you happen to be so much better all of a sudden?"

"Well, miss," replied the auntie, proudly, "Ah always done heah dat Virginny climate's a heap healthiah 'n de climate of No'th Ca'liny. Ah reckon dat sho' counts fo' ma change fo' de bettah."

SUGGESTION TO AND FOR MOTHERS

Children are wonderfully amenable to suggestion, good or bad. I have long contended and often proved that suggestion used intelligently by the mother is a most potent factor for

good, as thereby the most willful child may be made submissive, not by having the will destroyed, but by having it directed into proper channels. Through the same agency children may be cured of bad habits, undesirable traits, inattention to studies, etc.

The time to shape a character, the time when it is most susceptible to maternal influences, is during the natural—not hypnotic—sleep of the child.

"The night time of the body is the day time of the soul." The sleepy-time of the child is the impressible time. Any mother who has the highest interest of her child at heart will make almost any sacrifice to use that maternal, soulful influence at that most opportune time by herself putting her children to bed instead of committing them to the care of another, especially that of a servant.

"The soul of a child and, in lesser degree, of the grown-up man," says Dr. Frederick Van Eeden, "can be shaped by suggestive influence in any form; it can be bent, crooked, twisted, adulterated — morally and mentally — to an extent dependent on its degree

of plasticity, its inborn original force of resistance, and the power of suggestive forces at work."

The definition of suggestibility as given by Bernheim is "the aptitude of the mind to receive an idea, and the tendency to transform it into action."

The general opinion is that a person asleep is, for the time being, dead to the world; but a knowledge of the fact that the subjective mind never sleeps should make one careful of what he says in the presence of a sleeper. Natural sleep is not a condition of insensibility to external impressions, but rather a condition of inattention. The sleeper hears, but he does not heed at the time the suggestion is made. It is not difficult to introduce ideas to one's consciousness which shall make a permanent and deep impression through the subjective mind upon the objective, or waking, mind. Much depends upon the age and the disposition of the child. No one understands this better than the mother.

As a rule, the best way to approach the child is to say (as it is about to retire): "Mamma is going to talk to you to-night while you are asleep, and

you will hear and understand it all, but you will not awake." Some children will, of course, be quite curious to know why you are going to talk to them, what you are going to talk about, and why you don't talk to them when they are awake.

In some instances the mother may sit by the side of the bed and talk in a general way to the child ere it sleeps. While she talks in a quiet manner, the child, as a rule, soon becomes drowsy, and as it drops asleep the mother says: "This is mother talking to you. You will not awake. You will sleep quietly. You are now very quiet and restful. You can speak to me without awaking. Do you hear me talking to you now? Say, 'Yes.' You will not awake. Now I touch your lips with my fingers and you can speak. Say 'Yes, mamma, I hear you.'"

You should not expect the child to awake, but should it stir uneasily and open its eyes, the mother should not relinquish her attempt, but gently close the eyelids, at the same time suggesting again: "Nothing will disturb you; you will sleep quietly now, and hear what mamma says, because it is

all for your good, and you will be so pleased to do what mamma suggests."

It is well if you stroke the child's forehead gently, as this will have a quieting effect and accustom the sleeper to your presence. You should then proceed with your suggestions of those things that you desire to eliminate —disobedience, untidiness, idleness, untruthfulness, nail-biting, lack of application to studies or music, etc., whatever you feel the child most needs. Speak plainly but quietly, yet with sufficient positiveness to be impressive.

If you wish to exact a promise from the child you should say: "I want you to promise me that you will never . . . . . again. Say, 'I promise you, mamma, that I never will.'" You should repeat this several times. I have always found it most effective to use the *first person, singular,* thus having the affirmation made by the child, instead of having the mother say, *you* will do this, or *you* will do that. To illustrate: "I'll do as mamma wants me to; I'll not do anything to hurt mamma; I'll make everybody happy by being good to everybody."

These suggestions need not be confined entirely to bad habits, but to physical ailments and various bodily conditions. One of my pupils cured her little girl (a very small child) of enuresis. This was easily accomplished, even after guaranteed remedies and the family physician had utterly failed. Another mother cured her fourteen-year-old boy of a very bad case of stammering, cured him while he slept; and the boy does not know to this day how the cure was effected.

There are cases covering almost every phase of mental and physical conditions. I shall give one more and the means employed.

FOR CHILDREN BACKWARD IN STUDIES

My niece, thirteen years of age, brought me her card at the close of the school year, and I noticed that her marking was very low on one particular study. She informed me that she took no interest in the subject. Hence she made no effort in its preparation.

During the summer I would have

her take a nap in the afternoon, lying on the floor, as I read my paper. I told her I would talk to her while she slept. She said: "What are you going to talk to me about, uncle?" "Oh, something for your good." "But I won't hear you if I am asleep." "Yes, you will, and you will answer me, too, without awaking."

I began by saying, "You will sleep well and my talking will not disturb you. Do you hear me?" "Yes, sir," came faintly. "I noticed on your card that in one of your studies you had a very low marking. That will not occur again. You will take a great interest in that study; you will succeed in it; you will get a high percentage." "Yes, I hear you say [turning this now to *first* person, singular], 'I am going to study it, am going to like it, am going to succeed in it, and I 'm going to surprise and please my teacher.'"

I repeated these suggestions over and over again, each time that the treatment was given, and for many days in succession. She slept well. When she awakened she had no recollection of what had been said. The

impressions had been made and the subjective mind received them without any conscious effort of the objective mind; hence no objective recollection. Then you may ask, "What becomes of the suggestions made to the subjective mind?"

During the waking hours they rise above the threshold of consciousness, not as thoughts suggested by another, but as an inspiration, a desire, a determination, as emanating wholly from the subject.

In the case of my niece the thought found lodgment in very congenial soil and brought forth good results. At the close of the next school year she came home in great glee, saying, as she handed me the card: "See here, uncle! Here is my marking on that study I did not like, but I like it now. See, I have a very high per cent on it. Is n't it queer?" Of course, I thought it was.

SUGGESTION AS AN EDUCATOR

The value of suggestion in educational work is almost beyond belief. This applies not only to the child that

is deficient in some particular study, as has been shown previously, or diffident to study in general, but also to adults fitting themselves for their life work. This is especially true of those entering or having entered professional life—the minister, doctor, lawyer, actor, musician, artist, etc. The natural talent may be greatly developed by proper treatment at the hands of an efficient suggestionist. In short, there is no occupation nor profession for which one has an aspiration that the necessary inspiration cannot be evoked, and the inherent power set in motion by the true suggestionist. Inspiration comes from the inner self.

WHY REPEAT SUGGESTIONS

The question has been asked time and again, "If the subjective mind is intuitive, and if it is ever ready and willing to assist, and if it has such power over the human machinery, why do you have to tell it what you want when it already knows? And after you tell it once, why do you repeat and repeat and repeat, when the

memory of the subjective mind is perfect?

Of all those who believe in the power of prayer I would, in answer, ask this question: If God is, as all believers will admit, omniscient (all knowing), and if, as we are told, He is even more ready than are our parents to give good gifts unto His children, why does He, who knows our desires without our uttering them, why does He not grant them without our telling Him what we want? And having told Him once, why is it necessary to repeat and repeat and repeat?

The fault is wholly with us — just simply lack of faith. The repetition acts as an autosuggestion to us. All the doubts and fears and discouragements lie in the objective mind. If you can get rid of them by one petition you will never need a second. You did not get them all at once; you loaded up with them by degrees. Even when the things that have been are no more, you still will have need to keep in touch—the finite with the infinite—to prevent recurrences.

Therefore, every time the suggestion is made, it is for the purpose of

strengthening your objective mind that it may not interfere with the subjective, or soul mind, in carrying out your desire.

In the same manner, when you pray audibly (by yourself, not to be heard by others), your faith is increased because of the spoken words acting as an autosuggestion. When in great distress, you "cry aloud" (not loudly), because the spoken heartfelt petition relieves the over-burdened soul and strengthens you.

Remember, God is ever ready to help, but He helps only those who help themselves; the subjective mind (the mind of the soul) is ever ready, but it depends upon the attitude of the objective.

CAUTION TO MOTHERS

Do not speak disparagingly either to or of a child, especially in the presence of another. To speak of a child's faults upon such an occasion is to impress them the more deeply upon the child. To tell him he is stupid is to make him the more so; to tell him he is a coward is to exaggerate the con-

dition of fear within him; to tell him he is idle and good-for-nothing is to make him so; but to pick out the good points and to speak of them is to encourage him and make him forget the less desirable ones. The law of suggestion is absolute.

You may remember the story of the mother who, upon leaving home, and allowing her children to care for themselves during her absence, said to them, "Now, don't play with the fire, nor put beans in your noses, nor turn on the hose." When she returned she found that they had all played with the fire, had turned on the hose, and each of the children had a bean up its nose.

This was the result of suggestion thrown out by the mother; the contrariness of human nature asserting itself.

QUICK RESULTS

A good old Scotch lady in Cleveland said to me: "I have a son, a young man, who is at present home from college. He is unlike any other of my children. He has never made a confidante of me. I cannot go to his room

to talk to him when he is asleep. I cannot even approach him on the subject when he is awake. What can I do to bring about the desired results?"

I advised her to hold the thought (her desire) *on* him, *for* him, while the family were together in the evening, each employed as taste might dictate. She should be *apparently* occupied—reading, for instance—but, in fact, *really* occupied in holding the thought, with faith believing in its ultimate success.

She did as suggested. This was the thought she held: "I have never confided in mother [the thought held in the first person, singular]. I know I should. I will have a talk with her. Yes, I will."

This thought, held by the mother for her son, became a prayer, an earnest desire of the heart. She dwelt upon it when in his presence. The thought found lodgment in his subjective mind. It presented itself to his objective mind as an earnest desire on his part. He obeyed the promptings. Her prayer was answered. The mother love prevailed in the silence when it would have been ineffectual through

the spoken word. She reached the objective through the subjective. This was her first attempt at suggestion through thought transference. She was successful the first night. Think of it! Her first trial! Why? Because of the power of quiescent concentration that results from calm, unfaltering faith.

SUGGESTIONS TO THE DYING

Not only is this admissible but properly given under proper conditions may prove a blessing. The so-called sleep of the dying is analogous to that of the deepest hypnosis and is, therefore, susceptible to any suggestion, pro or con, inasmuch as the subjective mind is wholly withdrawn from the material side of life. The slightest whisper may act with great force for good or otherwise, for even a thought may be cognized by the one just on the borderland.

A physician should be on his guard as to his remarks in the presence of the dying. A few weeks ago I called to see an elderly lady—seventy-five years of age—of whom the doctor

had said: "It is only a question of time, as the death-rattle has already begun and she will probably choke to death." This was not a pleasant thought for either the mother or daughter of the dying woman to entertain; therefore, with the daughter's permission I addressed myself to the subjective mind of the dying mother with a countersuggestion to that made by the physician. Almost instantly the rattling ceased, the respiration became easier, and the end came quietly and peacefully, but not for more than twenty-four hours after the time expected, the prolongation being due to the fact that there was less expenditure of vital and nervous force as the result of the suggestion.

METHOD FOR ABSENT TREATMENT

It is not necessary that suggestion should be confined to small children nor to the sleep condition.

If you desire to aid one — mentally, morally, or physically — at home or at a distance, you may readily do so after you retire, or during any time that you can enter the silence.

When the objective mind is asleep or is in abeyance, the subjective mind (which never sleeps) is the more active. Therefore, just before dropping asleep hold the thought of helpfulness on and for the one whom you wish to benefit. You frame the thought according to the individual, and the needs.

What takes place? Your messages are received by the non-sleeping mind (the subjective) of the one to whom they are sent. It is not as a message coming direct from you, but indirectly. The recipient will be impressd during his waking hours to follow an impulse coming from he knows not where; an impulse that will be wholly the result of your desire; an impulse to spur himself on to higher aims, greater ambition, and the acquisition of hope and courage in place of fear and discouragement; an impulse to lay hold of every hygienic measure for the restoration of health; in other words, whatever you desire for him he will desire for himself.

A word of caution. To secure the best results it is neither necessary nor wise to inform the person of your in-

tentions, unless you are assured that he or she is in full sympathy with your undertaking; otherwise you will be obliged to work against possible prejudice and preconceived ideas. I must admit that much of the so-called absent treatment resolves itself into self-treatment, as in thousands of cases no thought whatever is projected at the time of treatment.

It is true many were helped by merely thinking they were being treated at a certain time and by a certain person; so effective is the power of autosuggestion. Absent treatment is all right when properly and honestly used. It has been greatly ridiculed in consequence of its misuse. It has brought wealth to a few persons who have gulled their victims by charging them so much "per" for treatments which have never been given, except in type-written formulas that were previously prepared for all cases of a similar nature; the results, when such there are, being due to the autosuggestion of the subject, not to any specially directed effort of the healer. In thousands of cases the "healer" knew nothing of the condi-

tion of the patient, knew nothing of the patient, and did not come in touch with him at any time, but simply "touched" him for so much a month.

There is no doubt that a wonderful potency exists in projected thought-vibrations when emanating from a highly trained mind.

Suggestions for absent treatment are of many varieties—as many and various as are the desires or needs. If the suggestions are properly made in the proper spirit and with sufficient faith, *there is nothing within the bounds of reason that will not yield.* This applies to any habit—liquor, opium, morphine, tobacco—that has seemingly fastened itself upon the victim. Through this mental process (suggestion) you can secure such harmonious conditions, such confidence, as cannot be secured in any other way.

None should doubt the power of the mind in making mental impressions after the recent developments in New York. Four well-known scientists held their fingers on an inclosed photographic plate and while so doing concentrated the mind in-

tently on a ball of surgeon's gauze lying upon the floor. When the plate was developed the object was plainly visible.

The amount of good that may be accomplished by projecting the right thought-waves is beyond the power of the human mind to comprehend.

A REMARKABLE CASE OF SUGGESTION

One of the most striking examples of the power and good results of suggestion has just been reported from Paris. A wild, vicious, criminal, hysterical creature has been changed into a good woman. A once abandoned girl of the gutters is now an excellent, devoted nurse in a Paris hospital. The change is due to the patient and untiring efforts of Dr. Auguste Voisin, of the Salpetriere Hospital. The wonderful change was brought about by suggestion preceded by hypnosis: suggestion whereby good ideas were conveyed to her subjective mind, which finally conquered the evil habits that had been acquired from bad surroundings and early misfortunes. It

is the more remarkable when considering the fact that she was born of the lowest class of parents in the rag-picking quarter of Paris, where she saw little in her girlhood but wickedness and brutality. She was in a deplorable condition—"a criminal lunatic, filthy, with a life history of crime." At last, while in the hypnotic condition, she was taught to feel regret for her past life and to form resolutions for reform. She seemed as eager to do right after her transformation as she had been to do wrong before her better self was evoked. She now displays qualities as marked on the moral side as she did previously on the depraved side. This case should serve as a lesson to those who are prejudiced against hypnotism or suggestion. (See Vol. IV, Hypnotism.)

A FEW EXPERIENCES IN HEALING

During my own limited experience in treating, I have been especially impressed with the fact that results depend on mental attitude. I have taken similar cases; for

instance, deafness. In one case of six treatments there was scarcely any perceptible improvement; in others, a complete cure in fifteen minutes. What was the difference? In the former, the lady remarked at the close, "Well, I really did not think it could be done, because the doctor says I am of a contrary nature; that which helps others never has the same effect on me." Lack of faith.

In the other cases, they *expected* results, and had them in one sitting. Implicit faith.

I have thus noticed that results have been speedy or tardy in proportion to the faith. While I have been unusually successful, I have not been always successful. I would not shirk the responsibility of the so-called failures, but the logical conclusion compels me to say that it must rest entirely with the one being treated, provided that the one giving the treatments understands the law—the supreme law of psychotherapy.

As a lecturer and teacher, the treating I have done is merely incidental, as I confine myself almost wholly to those who enter my classes; but I have

in this way treated thousands with marked success. The previous lessons are to the members of the class what the tilling of the soil is to the seed; better results are realized.

My first attempt at healing was very encouraging because of its complete success. It occurred long before the label of Psychotherapy was in use. It was in 1886—a case of epilepsy as diagnosed by the family physician—cured in fifteen minutes. The latent energizing principle of the soul was aroused, doubts and fears were removed, and as the clouds rolled away the young woman exclaimed, "I do not believe I shall ever have another spell,"—nor did she. Her faith did make and keep her whole.

Incredible as it may seem, I have cured cases of chronic rheumatism in one treatment of about fifteen minutes; one case in three minutes.

One case of a *doctor* with a stiff knee joint—not chronic—cured in one treatment of fifteen minutes, after which we walked ten miles up a canyon in Oregon.

One case,—the most remarkable,—a middle-aged woman, blind for twenty

years, who during all that time had not seen so much as an outline of her children; after two treatments of one-half hour each she counted the number of people in the room, described the color of a dress, and left the room unaided. Sight was restored and retained until a serious accident befell her.

She had been told, by another method of treatment, that she was not blind except as she *thought* she was blind. This mode of treatment, she said, did not appeal to her common sense. I assured her that we would waste no time in denying the evidence of the senses. She was indeed blind; but in her special case there was no need of her remaining so. There was a power, not extraneous, not in me, but in herself—a God-given power. This power when awakened could and would overcome the physical defect. Faith I must have; *her* faith; mine was sufficient. Doubts and fears and worries cannot live in the same room with faith. I further assured her that the linking of her faith with my implicit faith in that inherent power would, when sufficiently ener-

gized, restore her sight. "And it was so."

I have cited but a few out of the many extreme cases that have come directly under my care. This I have done with no spirit of braggadocio, but as an encouragement to those who heal and to those who are in need of healing. Insomnia, constipation, nervousness, dyspepsia, the functioning of every organ and gland of the body; these, all these, as well as mental conditions, yield readily to the power of suggestion properly applied.

Recognizing, as I do, the necessity of having the objective mind in abeyance, receptive to the suggestions, I always place the subject under very light hypnosis when the condition cannot be otherwise obtained. During this time I make my suggestions as the case demands.

As a rule I do not consider the deep hypnotic sleep either necessary or desirable for suggestions. The difficulties lie largely in the objective mind; therefore, to pass the subject into a state of objective unconsciousness would be to address the subjective directly, and thus lose the opportunity

to strengthen the objective, the seat of the difficulty. I even go so far as to suggest to the subjects that they do not cross the border-line separating the conscious from the unconscious, unless I wish to pass them into the clairvoyant condition.

Another point I wish to make clear. I do not think it necessary to know objectively the exact cause of the disease. Of course the cause must be removed ere the effect can be removed. The *subjective knows,* and if you yourself are sufficiently passive your subjective will direct your thought and words to fit the case.

Every treatment should be a mental, spiritual, and physical uplift. If your soul (Psyche) is not in the work, you would better drop the lesser part, therapy, of whatever form it may be; but the combination—psycho-therapy —is the greatest remedial agent the world has ever known.

Not Hypnotism, But Suggestion

By
HENRY
HARRISON
BROWN

Fifth Edition

PRICE 25 CENTS

"NOW" CO.
589 HAIGHT STREET, SAN FRANCISCO, CAL.

Books By Henry Harrison Brown

THE LORD'S PRAYER: A VISION OF TODAY.
124 pp. $1.00.

CONCENTRATION—THE ROAD TO SUCCCESS.
120 pp. Paper 50c. Postage 4c.

SUCCESS—HOW WON THROUGH AFFIRMATION.
102 pp. Paper 50c. Postage 3c.

THE SIX STEPS IN DEMONSTRATION. *In press.*

THE MASTER'S TOUCH.
64 pp. Paper 30c. Postage 2c.

SELF-HEALING THROUGH SUGGESTION.
60 pp. 25c. Postage 2c.

HOW TO CONTROL FATE THROUGH SUGGESTION.
60 pp. Paper 25c. Postage 2c.

NOT HYPNOTISM BUT SUGGESTION.
60 pp. Paper 25c. Postage 2c.

MAN'S GREATEST DISCOVERY.
60 pp. 25c. Postage 2c.

DOLLARS WANT ME! THE NEW ROAD TO OPULENCE.
64 pp. 25c. Postage 2c.

THE FOLLOWING ARE 10C EACH, POSTAGE 1C.

SIX TRACTS ON SEX.
(1) Friendship: The Third Function of Sex.
(2) Body-Building: The First Function of Sex.
(3) Procreation a Secondary Function of Sex.
(4) The Ultimate of Sex.
(5) Place of Sex in Race Development.
(6) Social Hygiene: Sex Education.

Healing Words of Jesus.
A Triumphant Democracy (A United States of the World).
What is New Thought? 5c.
Healing Card. 5c.

HENRY HARRISON BROWN

589 HAIGHT STREET **SAN FRANCISCO, CAL.**

Born in Massachusetts in 1840. Served in U. S. Volunteers during Civil War from August, 1862, until October, 1865. Taught school; worked upon newspapers; lectured in various fields for 17 years; was 7 years a Unitarian minister. I entered my present work of mental healing and teaching in 1893. Editor and publisher of NOW since January, 1900. I have thus gained *by experience* that which I teach in my books. I consider none of them of more immediate practical value than this little book. Grateful for the generous reception of former editons, I now send forth this revised and enlarged edition, trusting it will also win me as many friends as the former has done.

Truly Your friend,
Henry Harrison Brown

How To Control Fate Through Suggestion

By HENRY HARRISON BROWN, author of "Not Hypnotism, but Suggestion," "Man's Greatest Discovery," and editor of NOW. 62 pp., paper.

Price, 25 Cents

The principles dealt with are: Unity. Revolution. Tendency of Thought. Fate. Man. Logic. Matter. Evolution. Force. Spirit. The New Man. Finer Vibrations. All Knowledge Possible. Race Sensitiveness. Saviors. Progress. No Sickness. Liberty. Spiritual Gifts. Classification of Psychic Power. Love. Love's Pitch and Octaves. Concentration. Involuntary Concentration. One Power to Heal. Millennium Here.

Wonderfully helpful to all. Following is one of the many good things said of this book:

"The world is full of New Thought Literature. It is helpful and inspiring to read. The latest to come to me is: 'How to Control Fate through Suggestion,' by Henry Harrison Brown. It is worth many dollars to any one who will *live* its philosophy."

ELLA WHEELER WILCOX.

The power of Suggestion, which has been verified, controlled and admitted, has at the same time reduced the number of impostors and miracles of past time. The most unlikely phenomena have regained this veneer of reality. They are no longer contested, because they now appear to us natural, possible and verifiable.

JEAN FINOT, in *Century Review*, 1906.

Suggestion has but one purpose and it is the Master purpose of life; to develop the perfection of character, which is Self-Control.

" 'Do you control your thoughts? Can you control your thoughts? Do you wish the power of controlling your thoughts? Do you wish to learn the power of your thoughts? Then take a course in Hypnotism. Learn through it, that you can *think,* upon your body, pain or its immunity. That you can *think* upon yourself a mental state of peace or of misery; learn that you *can* control your thoughts and thus create any condition you desire; learn that through *voluntary concentration*—which is all the hypnotist can teach you to do—you can be "Master of Fate and Captain of your Soul." "

HENRY HARRISON BROWN, in *NOW.*

NOT HYPNOTISM, BUT SUGGESTION

A Lesson in

SOUL CULTURE

BY

HENRY HARRISON BROWN

Author of "How to Control Fate through Suggestion," "Man's Greatest Discovery," "Concentration," "Success," etc. and Editor of NOW.

So shall some Thought of mine yet encircle earth,
And puff away thy crumbling altars, Jove.

—*Lowell.*

Logic and Sermons never convince,
The damp of night drives deeper into my Soul.

—*Walt Whitman.*

A man for success must have ideas, must obey ideas, or he might as well be the horse he rides on. Of no use are the men who study to do exactly as was done before, who never understand that today is a new day.—*Emerson.*

To the

Young Disciples of Soul Culture

Who Made "NOW" FOLK Possible.

I hold the KEY
To Health, Success and Happiness.
Study me and find it.
Meditation will reveal it.
Apply it in Living.
Then all THINGS desired
are thine.

PROEM

YOU!

Were you to learn that in a certain vault was untold treasure, and that, could you find the KEY, it would be yours, what would you do?

Did you know that beneath your acres lie valuable mines of precious ore and only a certain amount of dynamite would rift the hills and expose it, what would you do?

Did some expert convince you that wells of oil lie under your field and only a certain drill would bore to it, what would you do?

Did you ascertain that a certain book held all the information to make you wise in your dealings with men; that it would make each waking hour happy and each sleeping one peaceful, and that only by a great sacrifice could you obtain it, what would you do?

You would sacrifice all you at present possess, for you would know that, possessing these, millions more would be yours.

You *possess now* all these treasures. You are able to pay for their revelation. Will you?

I.

I possess the Power that will bring the realization of your possession.

It is the only Power that can give this to you.

All that gold is yours. I have the KEY.

All those mines are yours. I have the POWDER.

All those wells are yours. I have the DRILL.

All that information is yours. I have the BOOK.

It is yours by birthright. You did not know it. It lies deep *WITHIN*. Knowledge is POWER. It unlocks the treasure. That Knowledge so long sought is found. Its name is WISDOM. That KEY, that POWDER, that DRILL, that BOOK, is *SUGGESTION*.

"It seems to me that most of the objection to hypnotism arises from a fear or prejudice against the name itself and from misconception and misunderstanding regarding its power (or rather lack of power) to produce harmful results. The best authorities have found that suggestion may be made quite as effective while the subject is awake as by the use of hypnotism, except in some peculiar and unusual cases, but there is no reasonable ground for the denial or condemnation of hypnotism by New Thought people.

"Hypnotism is only one form (a minor form) of suggestion and suggestion is the *method* by which all Christian Science, Divine Science and New Thought healing is accomplished.

"Affirmation for healing and self-development is simply self-suggestion and is most effective when the conscious mind is passive.

"Hypnotism is simply a condition of induced sleep, during which the conscious mind is in abeyance and the subconscious mind is free to carry out suggestions and manifest its powers.

"In the hands of the trained physicians of Saltpetriere Hospital in Paris, hypnotism has produced many almost miraculous cures, and modified and developed to a wonderful extent the nature of some of the criminal patients treated there. Many intelligent physicians in our own country have employed hypnotism in special and peculiar cases with success."

WM. E. TOWNE, in *Nautilus*.

PREFACE

Phenomena, under the name "Hypnotism," draw increased and deserved attention. For nearly one hundred and fifty years it has been known and, under various names, produced for amusement, mystification, study, or physical benefit. It has been best known as "Mesmerism" and "Animal Magnetism." It now has a literature of its own and occupies much attention in the secular press. Its friends are in every walk of life. Schools and mail courses of study are plentiful. It is destined to be a most powerful factor in the therapeutic, educational and reformatory growth of the new century. That these phenomena exist is now no longer doubted. Their importance is admitted by all who give the subject even a casual study.

The author believes that the principle involved in them is the most important man has yet discovered, that it is destined to produce greater changes in man and his environments than any previous discovery. Believing this, he is devoting his energies to assist the development of a proper understanding of this Principle in the popular mind. He believes it to be the one Thought needed to bring in the age foretold by prophet and priest.

His intention is to explain these phenomena, to show their harmony with all other perceptions of Truth. The Law that underlies these phenomena is more practical than the multiplication table.

But the author wishes to say, first of all, that he uses the word "Hypnotism" under a protest. The name is a misnomer. It comes from "hypnosis," meaning sleep.

Sleep is not necessary to the phenomena nor to receive benefits from their use. In but few experiments is sleep necessary. Besides, the word carries with it the misconceptions of a false theory. There is no such thing as "hypnotic power" or "hypnotic phenomena." The phenomena occur, but they are not hypnotic. They are not the effect of a power that the operator possesses, but are the effect of the subject's own mind. All the phenomena produced by a "hypnotic" subject are as honest as those produced by him in school, home or workshop and are as natural and normal as those—are really identical in origin. In a subject, they are artificially reproduced and exaggerated.

The only power the operator has is that which teacher, merchant, preacher, mother or friend possesses over others. It is what, in ordinary speech, is termed "Influence." The only difference between the "Hypnotic Professor" and men in other walks of life is that he understands and uses consciously the same power that men in other phases of life use unconsciously and instinctively. It is the object of this book to remove all mystery from Hypnotism, to prepare mental conditions for a clear understanding of the principle of Suggestion, in accord with which all phenomena of life occur, and to prepare the way for its application in daily life.

As I write this introduction, there comes to my exchange table a valued journal showing that its otherwise very intelligent editor has a misconception of the subject of Hypnotism. He says: "We are individuals and refuse to surrender the control of ourselves or our mentality to anyone." This book will show that when one shall understand what Suggestion is, he will see that, instead of a surrender of individuality, it is a development of individuality. It places him in full control of himself. Suggestion is the road to self-control. It is putting in-

to practice the law which it is man's province to bend to his Will, the law of Concentration.

To learn our powers and how to use them, is the province of education. There is no other way to self-knowledge equal to a knowledge of Suggestion. The end of this knowledge is self-control and self-control is the acme of character. Those who oppose hypnotism do so only through a misunderstanding of the law of Suggestion. "If one can thus destroy another's will," it is said, "then he can influence to evil and crime." Certainly, "If"! But that is impossible, as I shall later show.

As an expert, I declare that man has found no law of so much importance to his well-being as that explained in this book.

San Francisco, Calif.,
January, 1902.

There is limitation, model, and suggestion, to the very archangels, if we knew their history.

EMERSON, in *"Quotations and Originality."*

The best mind is that which is most impressionable. . . . A master can formulate his thoughts. Our thoughts at first possess us. Later, if we have good heads, we come to possess them. We believe that certain persons add to the common vision a certain degree of control over these states of mind; that the true scholar is one who has the power to stand beside his thoughts or to hold them off at arm's length and give them perspective.

EMERSON, in *"Natural History of the Intellect."*

PREFACE TO THIS FIFTH EDITION

A few years ago hypnotic exhibitions were a common form of stage entertainment. That phase of hypnotism, having served its purpose of familiarizing the public with the fact that there is in the mind a subtle power, has passed away. Hypnotism has been considered mysterious and dangerous because of the belief that this subtle power resides in the mind and will of the operator, who could use it, secretly and irresistibly, to the injury of his fellows. But we now know that this power resides within each individual and that it can be exercised only by himself and upon himself. We know that hypnotic phenomena are always present in the every day life of us all. And since every man is controlled by his own thought, he is in a constant state of self-hypnotism. In fact. all human expressions are forms of self-hypnotism. I am that which, for the time, I think I am. We know, furthermore, that the stage phenomena are but the exaggeration of ordinary and natural expressions. The discovery that all mental action is incident upon thought proves the truth of the saying, old as history, "As a man thinketh in his heart, so is he." This is but a statement of the one Law under which all men live—the Law of Self-suggestion. The phenomena which were at first ascribed to the hypnotic power of a few individuals, a power which was supposed to reside in them alone, we now know are the manifestations of a power that is resident in each individual and are due to the operation of the Law of Suggestion. This knowledge has become so widespread that comparatively little interest is now felt in stage hypnotism. On the other hand, there is an absorbing interest in the every day application of

the Law of Suggestion. Many cults have arisen, each of which, in its own peculiar way, applies this Law for a variety of purposes, especially for healing. But they still hold the old, false conceptions of the power and danger of hypnotism and are still inculcating the old fear of it. They are ignorant of the great Law of Suggestion, under which they do all their work. The best stage operator has no more innate power over his subjects than a babe has over a statesman. The power resides in the subject, and is merely his ability to control his own thoughts and voluntarily to accept as his own the thought suggested to him. The purpose of this little book is to set forth with the greatest clarity this important principle.

The reasons why hypnotism has been so misunderstood are easily discovered. The chief reason is to be found in the extraordinary character of the phenomena observed in the subject. These phenomena were so strange and inexplicable that they led to the false conception that they were due to the extraordinary and dangerous power of the operator. Another reason for the popular misunderstanding is found in the dishonesty of stage operators, who have not been content with real phenomena, but have supplemented their exhibitions with tricks and "fakes." Such dishonest operators have strengthened the common belief that one person may have the mysterious and compelling power to force others to act against their own will. I dare risk my reputation as a teacher on the affirmation that never yet has any hypnotist compelled another person to act against his own will. Such tricksters are the worst of present day criminals, for they teach the dangerous error that one person can be made subject, unwillingly, to the thought and will of another. There are hundreds of people suffering from the delusion that they are under the hypnotic

control of some other person. They are found in every stage of this delusion, from the simple one of fear to that of hopeless insanity. Every practitioner knows that these self-hypnotized persons are most difficult to restore to normal conditions.

Realizing the confusion in the public mind and knowing the dangers arising from the ignorant fear of hypnotism, I was inspired sixteen years ago, from my wide experience, to write this little book as a "mental disinfectant." Having daily evidence that there is still widespread ignorance of the importance and beneficence of the Law of Suggestion, I issue this revised edition—the fifth—trusting that the little book will continue its good work. Appreciating the kind reception it has had, I again send it forth, a modest candidate for public favor.

HENRY HARRISON BROWN.

San Francisco, Calif.,
February 14, 1918.

The Key to Wisdom, the Inlet to Power,

And the road to Success, are all found

In the Principle of Suggestion. . .

This discussion is based upon a philosophy, called "NOW" Philosophy, or "Soul Culture"

NOT HYPNOTISM, BUT SUGGESTION

TRUTH AND UNITY

Truth is a fixed quantity. Man perceives but does not create Truth. Truth and the Universe are Co-extensive.

It is not Truth and error; it is only more or less Truth. The Universe is One. This Universe is divided, by my Consciousness, into myself and that which is not myself. This division is purely a mental one; I make it when I say, "I AM." There is a larger part of the Universe of which I am not conscious. That of which I am conscious I shall call myself; that of which I am unconscious is variously named God, Energy, Force, Nature, etc. These are but names, and names are only symbols for that which is. I am not a separated portion of the Universe; I am a manifestation of the whole of it. Thus my recognition of Self divides the Universe, to my consciousness, into what I call "I," which is the Within, and what I call "Not I," which is the Without. This is the simplest of all philosophical statements It is as simple as Cause and Effect.

"I" AND "NOT I"

Through Sensation I am able to separate between the "Me" and the "Not me," between the Absolute and the Individual. Consciousness abides in the power to sense

that which is the Me, and distinguish it from the Non-me. Sensation is differentiated into five special senses. By means of these senses, I know that I am not that which I sense. I am the "I" which senses. Because I sense, that is because I feel, I think. I am something that feels and thinks. What is this "I"? It is not that which is felt and is thought about. We name it Ego, Soul, Spirit, Self. This is simply naming the "I AM." It names but does not explain. Now that "I AM," because I feel and think, the questions rise: Can I feel what I choose to feel? Can I think what I choose to think? It is with these questions that this book deals. If I can thus choose, I am a free man. If I cannot, I am a slave.

POWER OF CHOICE

Can I control the Non-Me so that it will make Me feel and think as I choose. Am I an independent individuality in the Universe where I can use, at will, the forces of that Universe? This is the most important question man has ever considered. Heretofore the answer has been, "No!" But the twentieth century opens with the answer, "Yes!"

SENSATION

How? To teach "how," is the object of this book. Briefly the answer is this:—The phenomena called Hypnotic, but which are the daily phenomena of Suggestion, when once their significance is known, contain this needed knowledge. To understand this significance, we must look, through the demonstrations of science, into the phenomena of sensation.

Sensation is the recognition by the Ego of that which

is on the without of itself—outside itself. Sensation arises from contact of the Within and the Without. What contacts? To science, all is motion. The Ego is a form of motion. The Without is a form of motion. All contact is through radiation from centers. These radiations are called, when passing through space, Vibrations. All contact is that of some vibration upon the Ego. The body does not feel; it is only the channel through which vibrations impinge upon the Ego. A body which the Ego has left does not feel. Dead bodies have no sensation. Vibrations differ in speed Pitch is the better word. Vibrations of different pitch produce different sensations. We call one sensation taste, another odor, another sound, another light, but these are only differentiations of the one sense of touch.

EMOTION

The begining of consciousness lies in Feeling. By it we are kept in touch with Unity, of which we are simply a manifestation. Unity is indivisible. Thus I, the Ego, am a necessity to Unity, for without an Ego there would be neither sensation nor thought. Individuality is manifest in Unity, through thought, born of Feeling. Whatever I sense, be it pleasure or pain, joy or sorrow, beauty or goodness, music or love, is produced in me as a response of the Ego to some vibration. This response we call an emotion. "E" means out; thus we have an outmotion to meet the "in"-motion; an involution and an evolution. When the Ego does not respond to the Vibration, as in very young children; in the blind, and in the deaf; there is in these neither light nor sound. But the vibrations from without, which would cause these sensations, were they received, still exist. Thus does the individual make his own world. The blind lives in a world of darkness, and the deaf in a soundless one.

KEY TO WISDOM

Can the individual who sees and hears refuse to see and hear? This is a question of more import than wireless telegraphy or aerial navigation. If one can so choose, he will see and hear only the pleasant. Happiness is ever his who shall achieve this power of conscious choice. To know how to choose and how to live in the world of chosen sensation, is the knowledge above all other knowledge. To possess it is to have the Key to Wisdom. This it is to be Self-Controlled,—to be the Master of Fate. This is to create each day the conditions we wish. That it can be done, thousands today, in their self-created conditions of health and prosperity, testify. Conditions may be as consciously determined and wrought out as are the statues and paintings in the galleries. This knowledge comes as all other comes,—from Mother Nature herself; from observing the phenomena of daily life.

RESPONSIBILITY OF CHOICE

Each person now, in ignorance of his power and of the laws of mind (and foremost among them is the Law of Suggestion), creates his body and his surroundings from his choice. Each day's conditions are the result of choices made without knowledge of results. As proof witness these and many similar common expressions: "If I had known more last year"; "Had I chosen differently"; "Had I forgiven"; "Had I bought or sold, how different my life would be." And one is condemned for his intemperance, his crime, his poverty, or his ignorance, "because he could do better," thus implying a belief at least in a limited power of choice, and a limited responsibility for the conditions of life. Every one realizes that his life would be very different today had he

made a different decision on certain matters a year ago. Thus do we shape destiny according to our intelligence. This proves the point I wish to emphasize: each one, whether he is conscious of it or not, creates his own conditions of life. Seeing it clearly in a few cases, we are compelled to say that it is the same in all. The cause of conditions is located within. Each person by his acts of choice in the past has produced the con litions in which he finds himself. And furthermore, by acts of choice he can change his present conditions.

CREATIVE THOUGHT

We have now only to apply the wisdom those facts of daily life teach us. All the choice comes from the one Law of Suggestion. Where lies choice? Not in sensation, the primal recognition of the Ego—of Self—and that which is not Self, but in sensation when it is transformed into thought by that portion of the nervous system which the Ego created for that purpose. It is in Thought that men differ. All feel alike. Sensation is one. The vibrations that make light in one cannot make sound in another. The sound once made, each person thinks his own thought, born of it. The car whistle causes the engineer and the traveler, the boy and the farmer, to think differently. In the wife of the engineer it may awaken emotions of fear; in that of the passenger, emotions of joy. Yet the sensation, caused by vibration on the ear, is one in all. But over sensations presides the individual Ego, and it decides how sensations shall affect him. He is king in his domain,—the world of Thought. "The kingdom of God is *within* YOU!" said Jesus. Thus is Thought the creator of that real world in which the Ego lives. Thought-created are all the conditions of life.

UNLIKENESS

Universal Energy is One. It manifests as Life. It is One in all men. Life manifests first as Sensation which is the same in all. But sensation is transmuted into thought, then all are unlike; they become individuals. The Indian, the Californian, the Mexican and the Chinaman have all had the same sun, soil, wind and water in California. How different the conditions of the four! What has brought about these different conditions? Simply the difference in their thoughts—the difference in the acts of choice which each one has made.

RESULTS OF THINKING

"Whatsoever a man thinketh in his heart, so is he," says an ancient book. So the Dhammapada, said to be the word of Buddha, says: "Whatsoever a man thinks, the result follows him like a shadow." Thinking determines the effect of natural conditions upon the man. Thinking determines how vibrations from the Without shall affect the Ego. Whatever the sensation, man, by Will and the use of Suggestion, has the power to say of it: "It is good."

FATE CAN BE CONTROLLED

"All is Good!" This Affirmation will change pain to pleasure; grief to joy; despair to peace. When feeling badly, dear reader, did you ever have some friend or some unexpected good come to you and thus change your thought and send all bad conditions from you? Once from your mind, they were from your body. Did you ever have a pain and have it leave when your attention was turned to something else? A common case is the departure of a toothache when the dentist's tools

are seen. This is all there is of hypnotism and all there is in the school of Mental Healing. By Suggestion, one is caused to think of something else and, when pain is forgotten, it does not exist. The strongest Suggestion for the time rules the individual. Can we think pain, can we think health, whenever we choose? Yes.

Each person has power, when he knows himself, to say what he shall feel and think. Otherwise, he is a leaf on an infinite stream called "Fate"; a machine wrought upon by some outside power. Within a certain limit, this power of choice and control is admitted. Now we remove all limitations, realizing that they are self-imposed. Limitations are the direct results of ignorance. Man has the power of Self-Control. All one needs is to learn this as he has learned elsewhere, viz:—by experience.

That one may realize this power, it is necessary for him intelligently to apply the Law of Suggestion. He ignorantly applies it all the time. He should use the intelligence the platform subject does when he sleeps at the word of the operator.

A DEFINITION

What is Suggestion? And what is *a* Suggestion? SUGGESTION IS THAT WHICH CAUSES A SENSATION OR A THOUGHT. A SUGGESTION IS ANYTHING USED WITH AN UNDERSTANDING OF ITS POWER TO PRODUCE A CERTAIN MENTAL RESULT WHEN ACCEPTED BY ANOTHER PERSON.

Suggestion is the objective side of life. The subjective is Affirmation. An Affirmation is a statement of Truth. Each person is controlled by his convictions of Truth. He cannot get away from these convictions. On arising in the morning, he sees a fog. The ther-

mometer tells him it is 20 above zero. These are Suggestions and he says: "It is cold." This decision is an Affirmation born of the Suggestion. The Suggestion produced a feeling which was transmuted in the brain to the Affirmation of Truth, "It is cold." But the rugged school-boy in New England would say as he saw the thermometer, "Oh, a jolly morning!" and off he would go for a December skate. Each makes his own world. The Suggestion awakens different thoughts in each, different emotions in each.

Suggestion being anything from without coming to the consciousness, it follows that, when a person acquires power over himself so that he ignores unpleasant Suggestions and receives only those he wishes, he has acquired the power of making his life what he chooses it to be. He then rules the "Kingdom" within. Like a king, he receives from without only that which he chooses and that which comes with the credentials of pleasure and health.

I AM POWER

Subjectively, as a manifestation of Unity, man is potential power in every direction. In the objective life he is only unfolding that which he is in the subjective. Being all potential power, why should he not affirm that power? Why limit the manifestation of the subjective "I AM" to the little power he has heretofore manifested? There is no reason, except habit. Let him say henceforth: "I am power! Since, by thinking, I have power to direct the manifestations of the subjective I, I will think power. I do that which I desire to do!" He who will so affirm, *will* do.

POWER OF THOUGHT

This Affirmation is Suggestion transmuted into Auto-Suggestion. This is the power by which the conscious man can, at will, through desire and reason, control the manifestations of his life. Thought is power. It is the power the Individual uses to direct the Absolute power in which he, as an Ego, as an individualized being, lives and moves.*

In Self-Suggestion, Auto-Suggestion or Affirmation (for they are all one), lies the Diamond Drill, the Powder, the Key, that the Book promised in the "Proem."

SELF-ASSERTION

Through the use of Affirmation, life can be made what one desires, because all conditions, whether of good or ill, are controlled by one's will, and the will works through Affirmation. Affirmation is the will in action, the Self asserting itself. Affirmation, which is the power the hypnotist uses, is the only power any one possesses.

Self-assertion is the key to character. Affirmation, to lift one from conditions not desirable, must rest upon that arch of character whose keystone is Self-assertion. Without that mental characteristic, there can be no success in any direction. Therefore one Affirmation includes all others—"I AM!" The Affirmations that follow this, that mean the Victory of Self over Fate are, "I Can" and "I Do!" The Will that uses these is a cultivated and concentrated one. Will that is scattered over several Affirmations at the same time means constant failure.

---

*The reader is referred to the author's work, "Man's Greatest Discovery," 25c, for a discussion of this fact.

THE "OPEN SESAME"

We have now reached the word of power, have found the "Open Sesame" to the hidden treasure of the Soul. It is the word, CONCENTRATION; one thought at a time. Pay attention to what you are thinking. Yes! this is the recognized key to success. But it is also the key to the failures in health, business and happiness. Worry, anxiety, fear, grief, doubt, are all evidences of concentration. The question turns on the kind of thoughts for concentration. Concentration upon the wrong thoughts produces all the evil. Evil is the power of an uncontrolled mind. The business man in business concentration has awakened genii that make him a slave. Such concentration is not the key to Peace and Victory. Concentration is the "Open Sesame," but the treasure is not his until he learns not only to open but also to close the cave, not only to release the genii, but imprison them at will. The opposite of Concentration is as important as concentration. This is the "Letting Go," the Giving up, the Relaxing, the Changing, at will, the thought upon which to concentrate. This is the secret of Success. This is the power the Hypnotic subject possesses. He has learned that which, when learned by any one, will relieve him of worry, fear, pain and disease, and will open to him, while in the flesh, the door of Paradise.

All this lies in those phenomena which have been used, heretofore, generally to amuse or at best by physician to relieve pain. The application of the Law is as limitless as human experience.

PHILOSOPHER'S STONE

Voluntary Concentration upon a chosen thought is something better than the long sought "Philosopher's

Stone." He who has acquired it, is Master. It is the secret of the power of hypnotic subject, of "Christian Science," and "Hindoo Fakir"; it underlies all occult phenomena of every name and is the secret of the success of men in every rank and walk of life. Is it worth attaining? Is it worth the time and effort? Can you afford to learn it? These are not questions for a wise man to consider. Can you afford *not* to have it? Remember, all possible power lies within the Ego, awaiting expression. The only safe ways of manifestation are those directed by Self. The more faith in Self, the more power. They who have influenced the world have been those who had faith in themselves. Self-Assertion led to CONCENTRATION. The Affirmation of success has ever been, "I CAN!"

Here is the quatrain worth memorizing for the Philosophy of Life it contains. It is from Mrs. Helen Wilmans:

"He who dares assert the I,
May calmly wait,
While hurrying Fate
Meets his demand with sure Supply."

Outside Emerson's essay on "Self Reliance," no better words than these have been uttered. To that essay I recommend the reader as we turn to another phase of the subject.

PROF. GATES' EVIDENCE

"But what has this to do with Hypnotism?" will again be asked. Everything. The phenomena under that name demonstrate the truth of all this philosophy. My words are as true, based upon these phenomena, as are those in the works of physics in our schools. Like the physical scientist, I go to nature for my facts. Telepathy has as clearly demonstrated Thought to be Force as have the experiments in the laboratory demonstrated elec-

tricity to be a mode of motion. Prof. Elmer Gates has demonstrated by chemistry that thoughts of envy, jealousy, hate, anger and all others we call evil, produce a poison in the system which ultimately causes disease. Thought controls bodily conditions. This again demonstrates the efficacy of Mental Healing.

Study the stage performance. Learn how to do it and then repeat it in your parlor, go farther and experiment upon yourself. Remove sensation from your body. Pierce your arm with a needle without pain. Watch the patient in the hospital as he submits to a surgical operation with only Suggestion as an anesthetic and thus learn the meaning of Suggestion in daily life. If the boy on the stage, the patient in the hospital, can at a word concentrate upon the thought of painlessness, what is impossible through intelligent use of concentration in daily life? The boy on the stage throws away the gold coin, saying, "Hot." Later you can see the blister upon his hand. Disease is created in the same way by thinking of it. Have not these phenomena a meaning for each person? Have they for you? What is the power that produces such marvelous results? Merely the thought, the Affirmation, of the person: "It does not pain me"; "I do not feel it"; "It is hot"; "It burns me."

PRIMAL MANIFESTATION

Thoughts are equal in power because they are all from one source. They derive their power from the subconscious. The difference lies in the individual's power of concentration. Whether it shall be directed upon one thought or diffused over many, is for each individual to determine, and that determination controls the conditions of his life.

Remember, Suggestion is whatever causes an emotion or a thought; it will then be seen that it is an everpresent factor in life. No intellect is possible where Suggestion is not—no conscious manifestation of mind until Suggestion calls its latent faculties into expression. The primal manifestation of consciousness is a recognition of Suggestion. Affirmation is a primal manifestation of self-consciousness. This is why Affirmations, or, what is the same thing, convictions of truth, govern life. Truth is only the Affirmative of existence as interpreted by the individual who affirms.

Each individual is therefore subject to Suggestions from without, until he shall learn, by experience, his power of choice. That power of choice can be developed only through doing and this doing we call experience. Each one has the power of Affirmation; and in the power of choosing Affirmations, lies the power of creating Destiny as desired. Fate ceases where choice begins. Desire, through choice, becomes master of life.

OBJECTIVE LIFE

All things center in the simple fact of sensation—I feel, and its corollary, because I feel, I think. Now affirm, would you be master, "I have learned what to think that I may feel what I choose, and I have learned not to feel or think that which I do not wish to feel or think." In this development is seen the necessity of the objective life. It awakens the Ego into a consciousness of itself. Without the objective, no manifestation of life; there would be only the possibility of life. Thus are the subjective and the objective one. They cannot be separated. And without argument, it is here affirmed that they are one *forever*.

It has already been asserted that each person has the power of choosing and of ignoring Suggestions. One

can at will determine his life. *At will* is used understandingly. These two words are mighty. When this statement is seen to be truth, it will also be seen that this is the most important fact mankind has yet found. Its significance cannot be measured for a century. This is the statement: When man knows his power, he will never more be the slave of circumstances. He will mould circumstances to his will. This is demonstrated by the simple phenomenon of the hypnotist's suggestion to his subjects. "You cannot open your hand." The hand remains fast because the Suggestion, taken as truth, becomes in him an Affirmation. He says: "I cannot open my hand." His saying so makes it impossible for him to open the hand until he shall say: "I can." This demonstrates the power of concentraton. The subject concentrates his mind upon the thought, "I can't open my hand." Since Thought is power, Thought holds his hand fast. He simply concentrates upon the thought and lets Thought, as a vibration from the Infinite One, have its way with his hand. It is a scientific demonstration of the Affirmation, "As a man thinketh in his heart, so is he." It also demonstrates something as important, that which makes the Principles underlying the fact practical: A MAN CAN THINK WHATEVER HE WISHES, AND CAN MAKE THAT THOUGHT A REALITY IN THE OBJECTIVE LIFE.

SOURCE OF POWER

This is the key to human destiny. This is the most important fact man has ever discovered. It means the evolution of all that now is into something beyond the dream of poet or the vision of seer. Each man can affirm and *be* that which he wishes to be. All he has to

do is to follow the lead of the hypnotic subject and choose, at will, the view of Truth that is to him most desirous, and then hold the chosen view in concentrated attention as the subject does—let it control him. The power of Thought is limitless.

All power comes from the sub-conscious. This sub-conscious is the Human Soul, the Ego. It does nothing that is not willed by the Conscious mind. The Sub-conscious is to the Conscious man the only fountain of power, intelligence, and love. The conscious man controls the expression of this fountain by his Will. To learn how to Will is the most important thing in education. When one has so trained his Will that it will seize upon a chosen thought with the same tenacity that it seizes in ordinary men upon a thought born of chance Suggestion, and will hold that chosen thought as long and as persistently as does he whose body fails under the unwelcome strain of worry, anxiety, fear, sorrow, remorse, and kindred conditions, then is that individual Self-Centered, Self-Poised, Self-Controlled. He will then hold closely thoughts of pleasure, success and health as realities; be the master of conditions. This is the condition temporarily of the hypnotic subject. It can be the permanent condition in life, and will be his who chooses determinedly what Affirmation to make and what sensations shall be born of the Suggestions that come to him from the objective life. The hypnotic subject has this power; he can accept or reject Suggestions. When the operator says "hot," he can laugh or can say "cold"; and what he says is so to him. He has then, and ever has, his choice. He chooses to accept the Suggestion of operator as Truth, and so choosing, he affirms that this dollar *is* hot and the thought produces the sensation of burning, and will, if persisted in, raise a blister.

This is the real, constant condition of every man. He accepts the Suggestions of the weather, business, social life, of economic, political, bodily and financial conditions and says "Yes" to them and affirms that he is cold or hot, prosperous or unlucky, well or ill, happy or miserable, lonesome or contented, that times are good or hard, and they are as he affirms. Life is to him only a list of Affirmations born in the Suggestions of the external world or from experiences which, by Affrmation, become again realities. These conditions are produced in him just as they are produced in the hypnotic subject. The Law is one, just as the flash of the electric spark in the laboratory is one with the lightning's flash. But there is this difference. The flash in the laboratory is under control of an intelligent Will and does a predetermined work. That in the bolt from the cloud has no conscious Will to guide it but follows the law of the Absolute, and it may destroy. So with Thought in the ordinary affairs of life. It works its way without being understood and directed; it tears down as well as builds up. When one shall learn to choose and to direct, as the subject on the platform has learned to do, then all Thought will be chosen to build up and to make happy. Suggestion itself is merely a blind vibration. Feeling is a blind, unintelligent response; but Affirmation is the act of a Soul, is the choice of an individual. To the extent that one exercises consciously this power of choice in his Affirmations, does he develop the one feature that distinguishes him from the brute and which makes him man--and that is the power of Self-control.

SELF-PROTECTION

That any one has consciously, even for a short time, exercised his power of choice in his Affirmations proves that it is possible for every one to do so. As the subject can, by his Will, make his body insensible to the prick of a pin, so may every person become insensible to pain. As one person can master, through necessity, a condition of weakness by an Affirmation, as in case of a mother when sick but recovering when her child is injured, so may all become immune to disease by refusing to receive a Suggeston that will result in disease. Your body is your castle. No vibration can enter it except through your neglect or by your invitation. Vibrations affect only body; they have no power over the Soul. Nothing touches the Soul except as the Soul through its will permits it. When anything is felt, one should refuse to think of it and should call the Will into activity and hold a pleasant thought instead. Then has the vibration done its work of creating happiness. Allow it to awaken a thought of pain and allow the Will to hold that thought of pain and disease results.

THE UNITY OF POWER

To attain this power, study the conditions necessary for the subject to receive his Suggestions and cultivate them until you can suggest and affirm to yourself that which you desire. All vibrations are merely vibrations until, through sensation, they are converted into Thought, just as vibrations of light that do not reach the eye are only vibrations of light, so we can close sensation to those which produce pain or sorrow; and then for us pain and sorrow will not exist. Thus is life made one continual round of peace. Study these phenomena labeled "Hypnotic" just as the phenomena of lightning

have been studied, and the results will be, to him who studies and demonstrates, similar to those that have followed in the wake of "Spiritualism," "Christian," "Divine," and "Mental" Science and the various schools of magnetic healing and metaphysics. All these are demonstrating some of the infinite possibilities that lie in Suggestion and its counterpart, Affirmation.

NOT OPERATOR'S WILL

Whatever may have been the past opinion, or whatever be that of many now to the contrary, it is *not* the Will of the operator that produces the phenomena of hypnotism. It is the concentrated Will of the subject. This fact is one that will, when its significance is understood, revolutionize all thinking and living and lift this study, now ignored by the cultured, into the first place in the Philosophy and the Art of Living.

The only principle concerned in the phenomena is the constant one of concentration upon an Affirmation that is the result of a chosen Suggestion. Three words form the shibboleth of the New Thought (which means the New Civilization), viz: SUGGESTION, AFFIRMATION, and CONCENTRATION. Understanding these, forms the true Science of Mind; properly using them, constitutes the Art of Living.

POWER OF WILL

The study of Suggestion removes from the mind all fear of evil results from the control of one mind over another, for such control is impossible. The Will can be used only by the individual upon himself. This is an important fact in this study. The person of the cultivated Will, the person of Concentration, always has the ad-

vantage of the one of diffused Will. Leaders, commanders, bosses, masters, operators in Suggestion, all owe their position to the fact that they use their Will upon themselves and give the Suggestions that will produce, when accepted by those of less concentration, the desired mental conditions. It is not a question of "can" or "can not" in the battle of life: it is the "will" and "will not." The healthful and successful WILL health and success. The others do not use what they possess in like proportion. All have equal power to do. It is the difference between doing and not doing.

The subject has learned to choose and to *will* himself into acceptance of the Suggestion for the time being, knowing that he can, at any time, will himself not to accept it. Having accepted it, it rules him. He has learned to lay it aside at will.

UNTRAINED WILL

Now, even a good Suggestion, if held too long, may, under changed condtions, become bad and produce ill effects, because the person has not developed the power to control his will. He has never brought it into obedience to his thought. He has not taught his Will to dismiss, at the proper moment, from his mind the suggestion that has once found lodgment there. His mind is so obsessed by the suggestion which he has once entertained that it can neither dismiss it, now that it has become injurious, nor admit a better suggestion that may present itself. It is of the utmost importance that you should be able not only to admit a suggestion but also to dismiss it at will.

So important is the fact that the subject is controlled only by his own will that, even at the risk of repetition, I wish to emphasize it. No person acts under the will of another. Even the hypnotic subject acts fundamentally under his own will because he has willed to submit to the commands of another, and has, at every moment, the power to accept or reject the commands laid upon him. I trust that this is so clearly seen that no reader of this book will hereafter claim that one person acts under the will of another, but that each reader will affirm that every person acts that which he wills to act.

INNOCUOUS

This fact understood, away goes the fear of hypnotism and all belief that one person can hypnotize another to commit crime. This is a groundless fear, a fear that arises in ignorance. The editor of the "Suggester and Thinker," in a recent number of his magazine, says of this belief in the evil of hypnotism: "It originated in fancy alone and belongs to the age of superstition, darkness and witchcraft and cannot exist today upon any legitimate grounds."

Every Suggestion that is repugnant to a person is by him rejected. This principle of Self-Protection is the most deep-seated in our lives. Ever alert to protect against danger are all the instincts of man. In this Art the reason is never appealed to. Should one attempt to reason with the subject to induce him to accept a Suggestion, every condition of acceptance would be destroyed. Perfect tranquillity of mind is the necessary condition for hypnosis. This tranquillity can be obtained only through consent of the subject. Consequently, whenever a Suggestion given antagonizes the Will or

Conscience of the subject, he passes out of the condition of subject and is under the control of his own Auto-Suggestion. It is utterly impossible for a person to accept another's Suggestion to perform an act which his conscience does not approve and which he would not freely do at his own suggestion.

This fact is well known to practitioners in Suggestion and to all careful investigators. Each person controls his own life at all times. He does nothing that he does not will to do. The only way one can be brought to do that which he has previously willed against is not by using hypnosis, but by using, when he is in a normal condition, the ordinary Suggestions in persuasion, argument or command. All of these are powerless in hypnosis.

SAFETY OF HYPNOSIS

In hypnosis, the frontal brain of the subject is, to a greater or less degree, inactive, and that portion of the brain, the cerebellum, most closely connected with the Ego, is most active. When conversing with a person in hypnosis, that is, with a somnambule, it is with the Ego, through the sympathetic nervous system, that all our conversation is carried on. One converses thus with the spirit of the man, and talks to the seat of moral consciousness. Conscience is supreme. Any Suggestion given to the Ego that runs counter to conscience is immediately repelled. An antagonistic Suggestion insisted upon will awaken the subject. A person in hypnosis is in the state most safe from evil Suggestions, for here all the external glamour is removed and only the enormity of such a Suggestion is present to the soul. Here lie the great possibilities of this Art in the redemption of man. From this source come the cures in all the fields of healing. The Soul is stimulated on the

way it desires to go. The operator, the teacher and the healer are helping the evolution of the Ego by opening to it the possibilities of the objective life. Illustrations of this fact frequently occur in my classes. I had a fine subject and, causing him to see a lizard, told him to take it up. He would not. I insisted. This caused him to awaken with a start. Another fine fellow was asleep. I suggested that, as we were on the street, we go in a saloon and get a glass of beer. "No, sir! I don't drink beer." "But come, you must." He awoke with a start. "What awakened you?" I asked. "I don't know, but some one hit me," was the reply. The impact of the two wills—his will and mine, for he willed against me—was to him like a blow.

SELF-HYPNOSIS—DEGREES OF

Now that hypnotism is being made the excuse for wrong doing, when the press is telling of persons marrying, stealing and committing all sorts of crime because they were hypnotized, it is well to dwell upon the impossibility of this so that all may feel hereafter that it offers no excuse for any evil. None can hide under this cloak. All these reported cases, if they are facts, are cases of Auto-Suggestion—of Self-Hypnotism. This is the condition in which all persons are whenever an abnormal condition is encouraged. If a woman thought a man was hypnotizing her and concentrated her mind upon that thought, she would pass into this condition through self-hypnotism, although the man not only had no desire to hypnotize her but was even unconscious of her existence. The press, by telling these stories, creates these imagined conditions in susceptible persons. Past education has developed a feeling of non-responsbility and fear in the indivdual which pre-

pares him to receive these Suggestions from the press and convert them into Auto-Suggestions and give them thus control over their lives. Herein lies the great evil of press reports of crime.

INVOLUNTARY SUGGESTION

From self weakness, therefore, comes the present fear of hypnotism. No person of self-reliance will claim to be hypnotized to do a foolish or an evil thing. The weak and the silly, the very ones that have not concentration enough to be hypnotized by an operator, are the ones constantly susceptible to self-hypnotism. They are constantly receiving Suggestions from the crowd they are in. They thus become the tool of the fashions, fads and follies of the day. They are the ones who need most to place themselves under the care of a good operator and, through his instructions, learn to concentrate and to protect themselves from the consequences of their willing but ignorant acceptance of Suggestions. Involuntary Suggestion, involuntary concentration, involuntary and unconscious choice, are to be avoided. When one has learned the Art of Suggestion, he knows too well the power of a Suggestion of evil; for, whether it is accepted by the subject or not, if he has given it with a desire to work evil, that evil will work in himself and as surely follow him as his shadow. No person is so chary of Suggestions which are not of good as one who has practiced the Art.

PRESS LIBELS

The daily press is scattering broadcast the seeds of this belief and fear in stories born in the brain of the reporter. They are his interpretation of facts. They are never sustained by the opinions of experts. When the re-

ported cases of evil are investigated, they are not sustained by evidence.

It has been reported that hypnotism has been made the plea of extenuation in courts. Never has a criminal been condemned, or a person acquitted, in this country upon the plea of hypnotism. Never has any judge considered such a plea. I will cite only one typical case. It goes its round in the press several times a year. Concerning it, I give as high an authority as exists upon the matter. Chief Justice Albert H. Horton, of the Kansas Supreme Court, in an address reported in the "State Journal" (Topeka), for April the 6th, 1895, says: "In affirming the conviction of Gray, no new doctrine was announced, no new rule of evidence established. *Hypnotism was not considered nor ruled upon in any way.* The reports are therefore wholly unfounded." But Judge Horton's statement is ignored and the lie of a reporter is made the basis for creating fear by teacher, preacher and editor.

EVIL ADVERTISEMENTS

But more injurious than the press reports are some of the advertisements of the teachers and schools in which the words, "secret power," "subtle power," and others are used to convey the idea that they have something mysterious and hidden and that the possession of this something will enable its possessor to influence any person to do his will, and will enable a graduate of their school to win easily everything he wishes in the battle of life. These claims are false. They mislead. No such power exists. All persons may cultivate and attain all that is claimed for "Hypnotism" and "Personal Magnetism" by a simple application of this Law of Suggestion.

The Soul of man is perfect. All Souls are alike. Each contains a spark of Infinity. All that any one needs is to let the god in him (the good in him) manifest. Suggestion opens the way. There is no patent right held by any person, or any class of persons, upon any method of this unfoldment. No method is universal. No limitations are possible. All is one principle. The principle of Suggestion is limitless and its methods will be adapted to the time and place. Once understand the Law of Suggestion, the Principle of Concentration, and you have entered the Holy of Holies; have the key to all the ancient mysteries; have knowledge of the way to the Occult Powers of the Soul.

SELF-PROTECTION

There are schools and teachers that advertise their ability to impart the power of "protection" against evil influences. Especially is this true of those who gather the press reports of the evils of hypnotism. With this claim they induce people to become their pupils. "Protection" from what? The Ego is all powerful. The only evil is ignorance. The only safeguard is knowledge. Knowledge of what? Of Self. No person can be protected from his thoughts. He must protect himself. All the possible evils there are in Suggestion are those that lie in thinking. A person must think. Now think no evil and none is possible.

PERSONAL RESPONSIBILITY

Thought is creative. It creates every condition in life. What shall I think? is the supreme queston that concerns every man. What are the results of thoughts and how are thoughts controlled? should be his questions.

No power, no statute law can protect a man from himself. Neither can they change him or cause him to think to order. As long as he fears, he must suffer the effects of fear; as long as he thinks pain, he must suffer pain; as long as he thinks he must be protected, he will be weak and will not protect himself from self-created evils.

Each person is responsible to himself for the thoughts he encourages. He cannot escape the results of his own thinking. If he will not keep harmful thoughts, "tramp thoughts," from his mind, he must take the consequences of such company.

The School of Suggestion is the University of the Soul. All other schools are of the intellect. This school opens the door through which to reach the Ego itself. None other is equal to it.

MISREPRESENTATION

Telepathy is now brought in as a ground for fear and people are warned in advertisements to go to certain teachers of hypnotism that they may learn to protect themselves from the evil thoughts of others. "This mysterious silent power," one advertisement reads. I affirm postively that it is more difficult to influence one silently to do what is not in harmony with his own thought than it is by oral Suggestion. A Suggestion is at all times a Suggestion. Its effect is the same whether given orally or telepathically. Those that do not conflict with desire, will or conscience will be readily received when silently given. It then does not meet with the intellectual limitations that are often put upon it when conveyed orally. But positively I repeat: no Suggestion repugnant to a person will be received telepathically. It falls as unnoticed, as harmless, as buckshot on an iron-clad.

THOUGHT HARMONY

When a thought is sent that meets with acceptance in the person to whom directed, then it will, if conditions are favorable, be responded to in action. A case in illustration:—A friend and I were riding in the street-car, and, as we were about to pass the home of a lady friend, my companion remarked: "I wonder if Mrs. B. will see us?" I thought it not likely. But, as the car stopped at the crossing, she came to the window and recognized us. Later we enquired why she came and she said: "While standing overseeing my dinner, I felt to go to the window." Our thought had reached her and, being a pleasant one, and her mind not being concentrated upon anything in particular, she was ready to respond. Had her mind been occupied with some necessary thought, or had our thought been unpleasant, she would not have responded.

AUTHORITIES

Operators in Hypnotism are unanimous in the assertion that no evils result from it. Earlier authorities think it "*possible*," but give no instances. Later ones declare that it is not possible. T. J. Hudson, the author of "The Law of Psychic Phenomena," says in a magazine article: "That hypnotism and its chief handmaiden, Suggestion, have been proven to be an unalloyed blessing to millions of the human race, can not be successfully controverted." Hudson Tuttle, as good an authority as there is in the ranks of Spiritualism, says of the trance which he calls "The Hypnotic State": "There is nothing in the trance which affects the physical senses; on the contrary, it gives them rest similar to normal sleep." Of all the European and American authorities that I have been able to find, none report any instance of evil

results. American operators who have hypnotized thousands and have seen some persons used as subjects for many years are most positive as to its harmlessness. The best authorities are those who, from the platform, give exhibitions, for they meet all classes and have the most extended practice. I have never conversed with one whose experience has not been that of my own, which is, that we can not cause a subject to do that which he *wills not* to do, or that which is morally repellent to him.

TESTIMONIES

Professor A. E. Carpenter, who probably has had as large an experience in this line as any living operator, told me twenty years ago that such was his experience. Professor Caldwell, one of the well known operators twenty years ago, told me the same. Professor Connet so taught his pupils. His law was: "You can not cause a pupil to work against his will, against his conscience, or to injure his person or his property."

H. L. Flint, as well known upon the hypnotic stage as any person in the Mississippi Valley, in a late interview reported in the press, said, in reply to the question as to whether or not a man can be hypnotized to commit crime, "I should say unconditionally, 'No! When under hypnotic influence, the subject's moral sensibilities are more acute than in the normal state and often, when in hypnosis, he cannot be made to do those little peccadillos that he will do when normal. It is correct to say that he will never do anything that he will not do at any other time, as far as his moral nature is concerned."

Thomas L. Adkin, dean of the New York Institute of Physicians and Surgeons, says in an article in *Practical Psychology*:—"I have hypnotized in public and in private about 15,000 people. I have seen

fully 25,000 people under hypnosis in the past fourteen years. I have never seen the slightest harmful results. Anyone who has had any practical experience with the subject is well aware that no harm can be done by hypnotic Suggestion. . . I was a subject myself for five years; was hypnotized thousands of times and, if harmful results were produced, I am not aware of it. . . I know a subject who has been hypnotized twenty or thirty times every night by different public hypnotists for the past twenty-five years, and he is just as sound mentally and physically as he ever was. . . To hypnotize a man, you ask him to think a certain way; or, in other words, ask him to concentrate his mind upon a certain subject. Now, then, if it does not injure one to think, it does not injure one to be hypnotized."
This is the testimony of experts and will close the case with every reader of this book.

SELF-SUGGESTION

Another phase of Suggestion, intensifying the position I have already taken, is that reported of several who have acquired a development of Auto-Suggestion so that, without operator, they can throw themselves at will into all the conditions they have seen produced in subjects. The press has recently told of a man who permits his flesh to be pierced without feeling pain. Any person can do this when he has overcome the fear of pain. Many of my students do it. By Self-Suggestion, they can produce any chosen phenomenon by simply thinking, "It is so!" thus demonstrating that it is the subject, not the operator, that does the work.
This power, when developed and rightly applied, lifts one out of any undesirable condition and enables him to make life each day, in body and in estate, to his order. For thought is creative, and whatever a man

builds in his thought and concentrates upon he will surely realize in his objective life. This is the Universal Law.

THE ONE LAW

The classic statement of this Law is:

I AM THAT WHICH I THINK I AM. Thought IS power. You should realize this and then direct your thought to build according to your desire. Otherwise it will run riot, as it does in most of us now. You must bring your undirected thought, which is now harmful to you, under the control of your will in order that it may work to your good.

POST-HYPNOTISM

Very convincing of the truth of our theory, are the phenomena called "Post-Hypnotic." While in hypnosis, a Suggestion is given the subject that he will, at a certain future time, do a certain thing. This also, through misunderstanding, has given rise to fears that the great lessons from it are not perceived. For illustration: A young man while asleep in my class was told that when he awoke he would find an unnamed article which the gentleman who gave the Suggestion had hidden. The young man awoke, took part in the exercises of the class for over an hour. Suddenly he went to a lady and asked her for the nickel she had. "What nickel?" Looking very stupid, he said, "I don't know. I only felt to ask you." She gave him the nickel which the gentleman had previously given her.

A DEEPER LESSON

Post-Hypnotic Suggestions can be carried out only on the plane of the intelligence or the conscience of the

subject, for these are the ever-present factors with which he deals. It is impossible to execute a post-hypnotic Suggestion which conflicts with the intelligence, prejudices, will or conscience of the subject. Consequently, the operator, in giving post-hypnotic, as well as other, Suggestions, is compelled to act within the limits of his subject's intelligence, conscience, prejudices, and will. But a deeper lesson is here. No thought is ever received by a mind that does not remain there to influence future conduct. The words of the teacher, the admonition of the mother, the advice of the father, the loving greeting of a friend, all, like post-hypnotic Suggestions, fall into the subconscious storehouse to influence future conduct. Let no person be discouraged because it seems his efforts for good are lost. No word that is upward tending is ever lost. It is a seed-thought of power sown in the soul. Sleeping or waking, words of love or truth react upon the Ego and bring forth fruit. "My word shall not return to me void," said the old prophet.

"One accent of the Holy Ghost
The heedless world hath never lost."

By the use of this principle of Suggestion, every latent power of the mind can be stimulated. It is the most potent and successful method of education. The retention by the mind of each Suggestion given it and the ability to intensify this impression by first rendering the intellect non-resitant by repose, offer the teacher an opportunity, by making Suggestions in the line of the ideal, such as is found in no other system of education.

THOUGHT SEEDS

Suggestions given in sleep are retained. Like seeds in the ground awaiting spring, rains and sun, they lie in

the subconscious, ready to spring into activity at the first opportunity. This is the reason why Mental Healing is so successful. This explains the cures by Suggestive Therapeutics. Post-Hypnotic Suggestion is the best method to cure all such vices as intemperance, profanity, worry, fear and licentiousness. All life, health and power within the Soul lie open to Suggestions given in sleep. To utilize this knowledge with children will hasten the "New Day."

SUGGESTIONS DURING SLEEP

The healing power of Suggestion during sleep is well known to practitioners of Suggestive Therapeutics. Its possibilities in the cure of habits are beginning to be known. The mother has, in the Law of Suggestion, power to wield for the intellectual and moral development of her child while it lies sleeping. By its use, she can then sow in the subconsciousness of her child the germ-thoughts of any study, can correct any habit, can awaken any slumbering power and can lead it in the way of her ideal. She has only to use this Art to make her home an Eden.

INCIDENTS

A young man, one of my subjects, was complaining that he could not perform his problems in mathematics. When he was asleep, I suggested to him that he was now in the Divine Mind and could learn and master the Law of Numbers and that he would do so. Before he awoke, he solved the problems and had no further trouble in the study. Had he dreamed this out in his ordinary sleep, it would have been a somewhat common occurrence. In fact, hypnotic and ordinary sleep are identical. They differ only in the way in which they are

produced. So he did in hypnosis, at will, only what others are doing without the knowledge of the Law.

I asked a lady to go to sleep and find a lost article. She did so. Others go to sleep and dream of finding lost articles. In her case, advantage was taken of the Law of Suggestion and at will she slept and found. A young man said that he was trying to invent a certain machine that puzzled him. I placed him in Hypnosis and said: "Now you are in the Divine Mind where all machines lie. Find that which you wish. If it is possible, you can find it." In a few minutes he said: "How simple that is." "Remember it when you are awake," was my command. He did so; it was a success. "A dream," one says. Yes, but a dream induced at will.

A lady was puzzling over an essay. In hypnosis, she found and, on awaking, wrote what she found. A lady was to take part in a concert but was full of fear. In hypnosis I suggested that she was confident of success and would, in the joy of the occasion, lose all fear. She enjoyed the evening. This condition can be readily cultivated so that one can bring from the subconscious, at will, any desired manifestation of Truth. A student of mine suggested that he would awaken in the morning with the material of a sketch that he had for some time wished to write. The morning brought the sketch. A student who had never written a poem thought that he would try Suggestion. Upon retiring at night, he concentrated upon the affirmation: "I will awaken and write a poem in the morning." Earlier than usual, he arose and the poem wrote itself. Thus will a knowledge of Suggestion lead the Conscious man to direct the manifestation of the Ego in his daily life.

SUGGESTION UNIVERSAL

This understanding of Suggestion explains the phenomena called "occult" and "spiritual." It explains the wonders of the Hindoo fakir and Buddhist priest, of Egyptian hierophant and Grecian sybil, of Roman seer and Mohammedan shiek, of mediaeval occultist and modern evangelist, of medium and clairvoyant, of psychometrist and hypnotic subject, of Christian Science, of Mental Science, and of the magnetic healer. All these find in Concentration under the Law of Suggestion their power. In the knowledge and application of this Law lies the future evolution of man. Some idea of what lies within the possibilities of Suggestion may be obtained from the consideration of the fact that the greatest reform movement during the last century, if not for several centuries, arose from its application, namely, "Metaphysical" healing. Under "Metaphysical" healing we include *all forms of suggestive therapeutics*, known under a great variety of names, such as New Thought, Mental healing, Divine healing, Divine science, Truth Students, Christian Science, Suggestive Therapeutics, and the like, all of which derive their efficiency from their use of the Law of Suggestion.

HISTORICAL DEVELOPMENT OF THE LAW OF SUGGESTION

It is interesting to trace the recent history of the development of this Law of Suggestion, which is the present-day form of Hypnotism. We can trace its theoretical, or philosophic, side from the philosophy of Emerson, and its practical side from the feats of Mesmer, through the theory and practice of Andrew Jackson Davis, and then through the phenomena of Spiritualism into all

the cults which today may be grouped under the head "New Thought," or "Metaphysical."

EMERSON'S PHILOSOPHY

Ralph Waldo Emerson in his Essays gave expression to that philosophy which has ramified into so many practical movements, all of which may be designated as "New Thought," or "Metaphysical."

MESMERISM, ANIMAL MAGNETISM

Although Hypnotism had been practiced for centuries under various forms in many occult religions or cults, for our purpose we need not go back beyond Mesmer. Hypnotism, as he practiced it, was called Mesmerism. Its theories and the practice of them were gradually enlarged and improved. It was also called "Animal Magnetism." Under this name it began to be frequently used in healing disease. From "Animal Magnetism," as practiced by the famous Dr. Quimby, of Portland, Me., two movements arose, one including all the forms of present-day metaphysical healing, or suggestive therapeutics, the other known as Christian Science. The former of these was developed chiefly through the writings of Dr. W. F. Evans, who was one of Dr. Quimby's students. In the course of a few years this movement has been split up into a large number of independent cults under various names, such as New Thought, Metaphysical healing, Divine healing, Spiritual healing, Mental healing, Suggestive Therapeutics, and so forth. They are all alike in principle, and differ only in their methods.

HARMONIAL PHILOSOPHY

Andrew Jackson Davis made a wide application of his philosophy to healing and other demonstrations of life in his system which he called "Harmonial Philosophy." While a little boy, having never read through a single book, Davis became a hypnotic subject and from this developed into a wonderful teacher. Through the hypnotic trance, subconsciousness was awakened and, in this state, he gave the lectures published under the title, "Nature's Divine Revelations."

Davis soon grew into an independence of his operators and developed what he calls the "Superior Condition," a better name than the phrase now in common use: "In the Silence."

SPIRITUALISM

The next step in advance is found in the movement called Spiritualism, which was a further development of the principles and practice of Davis. Spiritualism, through its magnetic healers and clairvoyants, gave a great impetus to "spiritual" and "mental" healing.

CHRISTIAN SCIENCE

Mrs. Mary Baker Eddy was, in her early career, a Spiritualist Medium. Dr. Quimby, of Maine, had, from his studies in Suggestion, then called "Animal Magnetism," discovered, that disease is a belief. He developed a system of mental treatment. Mrs. Eddy, then Mrs. Baker, was a patient and a student under Dr. Quimby. This was her start.

Accepting in its essentials the practice of Dr. Quimby, she denied the Law of Suggestion, although basing all her practice on it. In the place of this fundamental law

she put her interpretation of the Bible, which she worked out into an extensive system, which she called Christian Science. Her interpretation of Scripture may be original, but there is no originality in her practice, for it is nothing more nor less than an application of the Law of Suggestion.

WHAT OF THE FUTURE?

Such movements, resulting in so great blessings, affecting every avenue of modern thought and activity, are only prophecies of what shall be when Suggestion is generally understood. Enough has been accomplished to warrant all the assertions made in this book of its future use. We have now only to learn the Law and its mode of operation and then to take the same advantage of it that has been taken of other Laws, to make living a Fine Art.

LIFE A FINE ART

To live conscious of one's power; to understand the principle of Concentration and apply it; to understand the Law of Suggestion and make it a servant of Will; to affirm each day that which is desired as the only reality, this is to be an artist in life. To all who do this, Living has become A FINE ART. It is the object of this book to help its readers to become such artists. The whole secret lies in DOING. Many read New Thought literature and think that, as the schoolboy attains knowledge of letters and memorizes geographical names, they can attain this power of self-control. Not so! It comes, as comes the ability of the artist to handle the chisel and hammer in bringing the statue from the marble; as comes the power of the architect to place on paper the structure already in his mind; the power

of the mechanic to build a machine that he sees only in possibility; the power of expression that enables the poet to place in ever living words the bright ideal of beauty that haunts him. All these grasped the principles, first intellectually, then they practised until they made the channel within themselves for Thought to manifest under the direction of their Will. When they were ready, the statue carved itself; the palace drew its own design; the machine built itself; the poem forced itself into expression. The way had been prepared by *doing* at it, not trying, but by doing each day the very best possible and thus each day coming nearer to the real, which is eternally within the mind.

MATERIALIZED WILL

The piano player teaches us how to build a nervous structure to order. He begins awkwardly and bunglingly to fumble the keys. Each day his fingers learn better to obey his Will. After a long practice, they have learned to play what is in the mind. They find the keys and strike them without the conscious direction of the player. The Will has been materialized in them and has produced nerve cells which act automatically. After the nerves have thus been reconstructed under the direction of the Will, the player forgets his fingers, lets them do the mechanical part, while he plays mentally only. He listens to the internal music while the fingers play. John Fiske says: "This result is possible only because of a bodily change which has taken place in him. Countless molecular alterations have been wrought in the structure of sundry nerves and muscles, especially in the grey matter of sundry ganglia and nerve centers. Every ganglion concerned in the needful adjustment of eyes, fingers, wrists, or in the repeti-

tions of musical sounds has undergone a change more or less profound. It is enough for us to know there is such a registration of experiences." In relation to this "registration," he says: "Any creature's ability to perceive and act depends upon the registration of experiences in his nerve centers. It is either individual or ancestral experience that is thus registered; strictly speaking, it is both." Here we have all the physiological evidence necessary to demonstrate scientifically the facts of mental healing and to prove our theory as to the place and power of Suggestion. Experiences register themselves in brain and nervous changes.

MASTERY OF FATE

Each Suggestion affects the nerve tissue. It builds itself into bodily expression. The body is the materialized experiences of the individual. All experiences are those of thinking and feeling. The body is therefore only materialized feeling and thought. This is the greatest discovery man has made of his power over Nature. He can, by the conscious use of his Will, mold her into the semblance of his own ideal. He does now, as far as his body is concerned, mold her unconsciously. He is learning consciously to build not only body but environment to his ideal, through the use of his Will. Nature's side of the expression is in the building of the external, the physical, man. The director of the finer forces is Suggestion. Man's side is Auto-Suggestion, or the better word is Affirmation. We have found in this word, Affirmation, the Key to Power. Science found it for us. But she never opened the treasure-house. Now the key is placed in the lock. Will you turn it and possess? In this book are the necessary directions. They have been found by the effects of

Thought conditions artifically produced by Suggestion and Hypnotism, Suggestion being the Law, or principle, and Hypnotism, the Art. Hypnotic experiments have taught us the principle, power and use of Suggestion. Now become to yourself both subject and Suggester. You have learned the Law. All you need now is practice. Practice leads, through Demonstration, to Realizaton. This won, you are the Master of Fate.

THE MANIFEST IDEAL

No knowledge is superior to this. It is all that any healer, seer or conqueror ever learned. With this word, the portals of sense may be passed. Its word of power is AFFIRMATION. Its bugle call is SUGGESTION. To all who enlist under this banner, there is nothing but victory. Victory means Health, Success, Prosperity and Blessedness. The Way: AFFIRM THE IDEAL. HOLD TO IT THROUGH CONCENTRATION. LET THE IDEAL MANIFEST. FAITH IN SELF must give birth to the Affirmation, I AM! The end is Self-Control.

Formulas For Self-Hypnotism

AFFIRMATIONS

The benefit of this book lies in the fact that it has stimulated you to right thinking and right living. To think and to live rightly, you must constantly practice the principle of Self-suggestion. By practice, you are to make conditions to your desire. By CONSCIOUS WILL, you are to Master Fate.

If you find it difficult to hold the thought silently, it is a good plan to talk aloud to yourself. Treat the conscious man as subject and the "I" as operator. Persist until you yield to the Affirmation as the subject yields to the command of operator. Use these thoughts in any language to suit. Remember: According to the amount of Will that you put into your thought is the benefit received. Therefore, when affirming, throw back the shoulders, hold head erect, sit or stand firm, and *feel* the spirit of the Affirmaton. Use your own name in place of John Smith.

For Pain, say:—

Now, sir, you are Life! You cannot have pain. All pain has left you. Now go about your work. Attend to your business, John Smith, and I will attend to mine. I (Mind) built this body and I will restore it when you let me alone.

For Nervous Conditions:—

Now, sir, sit down in that chair and relax. Let go! Let go, sir, of old thoughts! Let go of your body. Forget

you have one. Imitate the baby, the cat and the dog when they rest. There now, you feel better already. There, sir, how much relaxed you are. You are rested already. Now keep peace in your mind and go to work. You are Peace.

For Insomnia:—

During the day, when you think of the night, say: "I shall sleep well tonight." When bedtime comes, say: "O, how sleepy I am. I already yawn." Now yawn, whether you feel to or not. Keep yawning till you do feel, then let it yawn itself and continue to say, "I'm sleepy," till you lose yourself in sleep.

For any kind of Sickness:—

Now, John Smith, you are Spirit, for I am Spirit and I made you. Spirit cannot be sick. Therefore this condition is purely a mental one and you are to change it. Ever remember that *I* am not sick. I am Life. Life manifests just as perfectly as you, John Smith, let it. If you will repress it by thinking disease and pain, then you will have them. Now you have forgotten them and only remember that I am LIFE. This you will repeat till I have made your body over anew: I AM LIFE! I AM LIFE!

For Discontent:—

Now, sir, you have everything you desire. Life is yours and Life contains all. You are Contentment.

For Poverty:—

Well, sir, you have all that is. You have Life and all that Life needs. God is within you. God is all! Let God manifest as He will. Let Life manifest. Polarize yourself and draw what you desire. Stop saying, "I am

poor." Say, "I have all. I am rich, for I have all I can use." Stop this economy. It will lead you to the poorhouse. I cannot lead you to things you wish when you fill your mind with these thoughts of poverty. Hereafter, keep full of Faith in the Good. Call your own to you by this Affirmation. I am with you and I am Power. Attend to your business of using to your desire what you have. Use it *now*. It is my business to bring more when this is gone.
The Affirmation, My SUPPLY IS INFINITE, will cure all poverty when it becomes Faith.

For Bad Habits:—

To cure any bad habit, say to yourself whenever you treat yourself or whenever you think of the habit: You are the Master of Self. You do just what you desire. Tobacco has no power over you. (Or beer, or worry, or anger, or gossip, or fault-finding, or argument, or talking of your pains or troubles. Use any one that fits the case.) You are temperate in all things, for I, the Soul, now guide you. Tell yourself: "Sir, I am Master." Affirm: "This old habit has passed from me. I love the good. Good fills me so full that there is in me no place for anything else. I am happy for old things are passed away."

For Fear:—

Fear is the one cause of all the evils of life. Use this formula in its thought, changing the words to suit:
I am fearless. All is good. No evil can come to me. I am courage. I am guided from within. I can make no mistake. I have banished all fear. I trust myself. I have confidence in myself. I rely upon myself. I am equal to any emergency. There is for me protection at

all times. No evil can come near my dwelling. I am fearless.

Post-Hypnotic Self-Suggestions:—

Have you forgotten something? Then say: "I know. Be still. It will come to me." Then forget that you wish to know and LET it fall into the mind. There is something you wish to decide upon or wish to think of; say: "When I awaken in the morning, I shall know what to do; I shall know what to say; I shall know what to write; I shall have the solution in my mind." By these Post-Hypnotic Suggestions, you may call up from the subconscious anything you desire.

L'Envoi

For the present, we part company. The subject is only opened. We have much to learn, much to Demonstrate. I promised to do a part. It is done. I have given you the Key. It is yours to use. I know the treasure that awaits you. Congratulating you on your POSSESSION, I leave you to the Joy of Self-Control attained through Self-Suggestion.

DOLLARS WANT ME

The New Road To Opulence

BY

HENRY HARRISON BROWN,

Editor of NOW,

Author, Lecturer and Teacher of wide repute.

New and Enlarged Edition—25 cents

The editor of "NOW" in a delightful little treatise on financial success, "Dollars Want Me," is telling the people to live every day in the thought that shining ore and rustling greenbacks are hurrying to find them.—*Ella Wheeler Wilcox.*

A gentleman in New York City writes: "Your little book, 'Dollars Want Me,' recently came into my hands. I have read it several times with much interest and benefit. You could have no doubt written a much larger volume, but with difficulty could you have said more. I have read many works along these same lines, some of them containing hundreds of pages, but received greater benefit from 'Dollars Want Me' than from all the rest combined. The secret of the book in your fundamental Principle is the exact reverse of the others. *Spirit attracts! Will pulls or grasps.*"

He looks at the Dollar in a new light and gives us a new theory, declaring "The Dollar is the willing slave of the man who thinks rightly." The style is trenchant. The right word seems to have been chosen to convey the desired meaning.

—*Boston Ideas.*

The best financial treatise of the century.—*A. N. Y. City Banker.*

This essay is instructive and cannot fail to do good.

—*Banner of Light, Boston.*

A mental tonic to discouraged souls.

—*Progress, Minneapolis, Minn.*

It tells you how to fish for the dollars and catch them.

—*Occult Truth Seeker.*

If you want stirring, practical and new ideas, send for it.

—*Occult Digest.*

"Dollars Want Me" has attained a good deal of notoriety, which it richly deserves.—*The Talisman, London, Eng.*

New Thought Books

By Henry Harrison Brown

Without doubt the books advertised on the inside cover page of this edition are the most successful and helpful New Thought books ever published. The student who is seeking conscious spiritual advancement will make no mistake if he purchases every book on the list. They are, in fact, text-books in the fine art of living, for they not only deal with fundamental principles but they also give practical instructions and directions for applying them. They show the creative power of constructive thought. They explain how to use the law of suggestion in building your ideal and in realizing it in your daily life. They will enable you, by right thinking, to lift yourself out of untoward conditions and create for yourself those conditions which will insure for you health, happiness, and success. If you are *interested* in developing your personality, your individuality, YOURSELF, these books will help you.

Read the following endorsements of these books:—

ELLA WHEELER WILCOX says: "The world is full of New Thought Literature. It is helpful and inspiring to read. The latest to come to me is: 'How to Control Fate Through Suggestion,' by Henry Harrison Brown. It is worth many dollars to any one who will *live* its New Thought philosophy.

—*N. Y. Evening Journal.*

J. STITT WILSON, well known editor, author, and New Thought teacher, writes: "Your books are unique and to the point. They have the breath of life in them. I will bring them to the notice of my classes."

GRANT WALLACE, in his valuable editorials for the evening *Bulletin*, has twice referred to this book as "a very fine little book" and recommends it to his readers as a text-book on Suggestion.

EUGENE DEL MAR, Editor of *Common Sense* and author of "Spiritual and Material Attraction," writes: "The truths are very clearly expressed and well presented. The book is in every way quite readable."

"Self-Healing Through Suggestion"

By Henry Harrison Brown, Editor "NOW"

PRICE 25 CENTS

(64 Pages; 9th Edition)

This is by far the most plain, practical and ready Text-book of Metaphysical Healing on the market. Since its first publication in 1904, more than 10,000 copies have been sold. Its sale is constantly increasing.

HERE ARE SOME SPECIMEN OPINIONS OF GOOD AUTHORITIES:

"Delightful as well as helpful."—*Progress,* Minneapolis.

"As good on this subject as can be found."—*Light,* London.

"Clear, concise, forcible, inspiring."—*Exodus,* Chicago.

"Mental tonic which one feels as he reads."—*Unity,* Kansas City, Mo.

"A hand-book for daily living."—*Banner of Light,* Boston.

"Worth a cartload of 'Dr. Somebody's Domestic Medicine'."—*Dr. J. H. Tilden in Stuffed Club,* Denver.

"Rules so simple that a child might read."—*Fulfillment,* Denver.

PREFACE.

THIS book, the title of which will, perhaps, scare those who fear novelty, is not a work of imagination, but of experience. A multitude of facts are set forth herein, that have been observed as well by the author himself as by sundry experimenters. It is a collection of facts, and nowhere else can you find brought together so many data. But it is not enough to accumulate facts—the facts must be rightly observed. In this respect Mr. Ochorowicz's criticism of the facts he has witnessed, or that he cites from the accounts given by other scientific men, is as rigorous as is called for by a subject so difficult. The most notable thing in his work is the resolute, unflagging determination to weigh all objections, to put away all causes of bad faith, whether conscious or unconscious, to take note of the difficulties of the problem, sometimes magnifying them, and not to be content till every possible cause of illusion has been removed.

The task was difficult, and it is much to have attempted it under conditions so stringent.

To demonstrate mental suggestion it suffices to eliminate two causes of error :

First, the error due to fraud. And when I say fraud, I do not mean willful deception plotted, contrived, studied beforehand—that is very rare ; but unconscious, automatic fraud (so to speak) produced by the natural tendency that is in all of us to wish to make an experiment successful when once we have taken it in hand. Hence, we must first of all make sure that no involuntary indication can have been given; in other words, that there has been no word or gesture or touch that could lead the person that answers to give preferably such or such response.

The second cause of error is chance. Chance often brings about amazing coincidences. Now, mathematical certitude is never attainable in cases where chance may play a part ; nevertheless, there is a moral certitude resulting from the continuous success of many experiments, the probability of any one of which is weak.

Mr. Ochorowicz has sought to eliminate these various difficulties; he finds a certain number of cases which he regards as conclusive—

and I think I may say that he is pretty exacting in the matter of proofs. In consequence of certain decisive experiments he has reached a conviction, and naturally he strives to make his readers share it with him.

And yet I do not think that his book, strong as it is in proofs, will convince all, or even many persons. I know too well (from my own experience) how difficult it is *to believe what we have seen* when it does not accord with the general tenor of our thoughts, with the commonplaces that underlie all our knowledge. A fortnight ago I witnessed such or such an astonishing fact, and I was convinced. To-day I toss my head and begin to doubt. Six months hence I shall no longer believe it at all. This is a curious anomaly of our mind. To produce conviction, it is not enough that a fact is proven logically and experimentally; it is necessary, furthermore, that we, so to speak, become intellectually habituated to it. If it clashes with our routine, it is rejected, spurned.

This is what is commonly called "common sense." Common sense it is that makes us reject all new and unexpected thoughts; that regulates our conduct and governs our opinions.

And yet this much-lauded "common sense" is little better than a routine of the intelligence. To-day's common sense is not the common sense of a couple of hundred years ago, or of a couple of thousand years ago. A couple of thousand years ago it was common sense to believe that the sun revolves round the earth and at even sinks into the ocean. A couple of hundred years ago it was common sense that one cannot in one day send a message to Pekin and receive an answer; but to-day common sense says that one can send a telegram thither, answer prepaid. To-day common sense commands that an army of a million soldiers be maintained, with five million muskets. Two or three centuries hence will not this common sense seem astounding absurdity?

Hence, if mental suggestion is opposed in the name of common sense, the common sense of the present year is meant, for the common sense of ten years hence will have quite other tendencies. It is only a question of time, and I dare say that after a few years this idea, having made its way into people's minds, will be found quite matter-of-course. People will, perhaps, even marvel that we should have found so much difficulty in accepting it. Do we not see the immortal discoveries of our great Pasteur, though proved by a superabundance of demonstrative experiments, nevertheless meeting an astonishing amount of opposition? What stronger evidence is needed of our incurable routine?

Not that I consider mental suggestion as rigorously proven once for all. Certainly not. Strictly demonstrative experiments are rare. In general, when they are conclusive (by concordance of results) they

are not irreproachable in other respects ; and when they are irreproachable, they are not conclusive. But some there are that are at once irreproachable and conclusive ; they will be found set forth in this book, and the reader will be able to judge of their importance.

After the facts, the theories. Of these there are many, but to me they do not seem to be of any great importance. The essential thing is to establish this fact, that *independently of any phenomenon appreciable by our normal senses, or by our normal perspicacity, how quick soever it may be supposed to be, there exists between the thought of two indididuals a correlation such as chance cannot account for.*

The demonstration of this proposition is, to my thinking, the fundamental point. And though Mr. Ochorowicz and others before him have amassed proofs, these do not produce absolute, complete conviction, but only doubt : so strong in its action upon our ideas is the influence of routine and of habit.

But whatever the opinion ultimately formed as to the reality of mental suggestion, it ought not, I think, to influence one's judgment as to Mr. Ochorowicz's book. Everybody, it seems to me, must recognize his sincerity, his perseverance, and his contempt for ready-made opinions. One feels that he has a passionate love of truth. That is an encomium that every man of good faith will appreciate.

CHARLES RICHET.

PART I.

EXPERIMENTS AND OBSERVATIONS OF THE AUTHOR.

"THE MAN WHO, OUTSIDE OF PURE MATHEMATICS, PRONOUNCES THE WORD IMPOSSIBLE, LACKS PRUDENCE."—ARAGO, in his *éloge* of Bailly.

THE limits of the possible are receding. The experimental method, after having founded positive psychology, is itself introducing us into the domain of the miraculous.

"Hypnotism" is henceforth part and parcel of science, and "suggestion," which produces most of its wonders, no longer surprises us; on the contrary, we constantly refer to it as explaining other phenomena still harder to understand.

Yet with *mental* suggestion the problem grows complicated. The explanation offered by the Commission[1] of 1784, viz.: "imagination and imitation," no longer suffices. One loses one's way; one seems ready to spurn science and to go headlong into occultism.

This limit once overpast, and mental suggestion accepted, may we flatter ourselves with the thought that there is some other phenomenon still more extraordinary to study?

But what matters it? Truth has nothing in it to make science afraid. This truth may even be absolutely at variance with current opinions, but none the less is it worthy of being studied with care, for nothing is so helpful to progress as a discovery that contradicts dominant theories.

But—is this a discovery? Is it a truth? That is the whole question.

Let us for the nonce put away scruples; let us double our habitual precautions, our tests, and let us examine the facts. An experiment

[1] Appointed by the French Academy to investigate "Mesmerism."—*Translator*.

is always instructive, even when it involves an illusion. Saved from the trouble of explaining the experiment, we shall have to get at the illusion; and if we succeed in accounting for that, why there is a result at all events.

And now, kind reader, if we are agreed as to principles, let us begin our little journey in search of a phenomenon in Mental Suggestion.

CHAPTER I.

APPARENT MENTAL SUGGESTION.

I MUST, first of all, confess that a year ago I did not believe in mental suggestion—not only did not believe in it, but the question did not to me appear to be important enough to warrant a special study. Yet several times I had tested the alleged action of thought upon a certain number of subjects.

First at Lublin, in 1867,[1] I experimented on a youth of seventeen, one pretty difficult to endorm,[2] but who, once in the somnambulic state, presented certain interesting phenomena.

For example, he would recognize any person of his acquaintance who might simply touch him on the back with a finger. Once he distinguished in this way as many as fifteen persons, one after another; and I must add that some of these persons entered after he had been endormed.

Though he showed a little hesitation with regard to persons that did not belong to the circle of his habitual acquaintance, he always distinguished my touch from that of every one else; and once he recognized a lady that had entered unknown to him, and whom he had seen for the first time several days before.

How could he do it?

As for the difference between the magnetizer and a stranger, it is very clearly recognized by many somnambules. The magnetizer's touch is to them either agreeable or indifferent, while the touch of any other person causes them pain. Why? Because these persons, say the magnetizers, are not "in rapport" with the subject. But that phrase does not tell us much. What, then, is "rapport?"

To state the question clearly, it is first to be observed that this phenomenon does not exist in "hypnotism" properly so-called. Let an hypnotized subject be touched by whomsoever, and if that touch

[1] That same year appeared my first work on "Magnetism" (Warsaw, 1867, *Gazeta Polska*).

[2] In French, *endormir*—to put to sleep; to put in the magnetic or the hypnotic sleep.—*Translator.*

causes him pain, then the touch of all other persons will have the same effect. He hears either everybody or nobody, obeys everybody, and can be awakened by any one.

It is not always so in the magnetic sleep, so-called, produced not by an inanimate object (a shining button, for example), but by a magnetizer, and especially by passes.

Now, every person has his own way of touching, and when one is accustomed to it, one readily notices the contact, the warmth, or the pressure of a strange hand. Some domestic animals, cats especially, will not suffer strangers to fondle them. If we stroke with the hand a sleeping cat that shows this idiosyncrasy, we easily recognize the fact from the difference in the reflex movements. The cat stretches herself out at full length languorously if it is her mistress that strokes her; if it is a stranger, she awakes dissatisfied and runs away.

The isolation in which the magnetized subject exists, and the possibility of his concentrating his attention better than in waking, facilitate this differential sensibility. It is strengthened by exercise, by habit. The subject takes those impressions best to which he is accustomed; sometimes even they become for him a need, an agreeable necessity, whereas unexpected and unwonted sensations confuse him.

But when there is question of distinguishing between strangers, this explanation seems no longer sufficient, even though we suppose molecular differences of touch—differences probable indeed, but not proved; which, besides, would have to be known beforehand, through habit, so that the subject might from them infer correspondence between a certain physical sensation and a given psychic personality.

Have we, then, here mental suggestion?

To recognize a person is to recognize in particular his *psychic* personality; that is, to recognize that living whole, inwardly active, whereof the external tactual manifestations are but a weak reflection. If, then, it were proven that the *ego* of a person can act upon the *ego* of the subject, that were a direct explanation, and it would be relatively adequate. The person touching thinks of himself; his mental state may be represented by an affirmation ("It is I") and a question ("Do you recognize me?"). All the persons present are looking at him, and, of course, thinking of him; hence, the whole company influences the subject, and this influence constitutes suggestion.

But if such an explanation is to be accepted, mental suggestion must be proved to exist, while these experiments are far from proving it by themselves. Hence, I turned to another explanation, more natural, indeed, though rather complex, *viz.*, that there was suggestion on the part of the company, but not mental suggestion. The subject was blindfolded, but as I called his attention to the people around him he could hear all that passed; he was at home, habit made him familiar with every possible noise of doors, furniture, floor; he was

intimately acquainted with the eight or ten persons present before his sleep; those who, at a given moment, did not take part in the experiment would freely exchange a few words in a high voice, while the others would request silence; the hearing of familiar voices enables one pretty accurately to determine the position of different interlocutors; and the noise made by the unavoidable changes of place helps one to complete or to correct one's judgments as occasion may require.

All these inductions may have been perfectly unconscious. In some respects we are better observers in dreams than in the waking state. The imaginary scenes of our dreams represent persons of our acquaintance in strict accordance with their characters and habits, reproducing their favorite sayings, and no end of physiognomic signs that our conscious observation takes no note of. Hence, it well may be that a somnambule, who has no distractions, whose whole recollection and whose every sensation contribute to one single perceptive act, can make out better than we the connections of certain signs.

The only fact that struck me as rather unaccountable, was the somnambule's recognition of the lady whom he had seen only once; but that incident presented some peculiarities of a kind to serve as pointers. The rustling of a silk robe behind his chair betokened to the subject a woman, and she a stranger, for the women of the house had no such robe. She hardly touched him, thus plainly showing timidity; *ergo*, more likely a spinster than a married woman; of the young ladies likely to come to the party in a silk gown, Miss W. stood among the first; *ergo*, it is Miss W.

Consequently, in the facts described, we have only *suggestion by conjecture*.[1]

Here is another experiment made upon the same subject, and apparently still more extraordinary. The problem was, to determine whether there was vision without the aid of the eyes.

I take up a book at such distance from the subject that he cannot see what it contains, and I open it anywhere. I then bid him read.

"I do not see clearly," he answers. I suggest to him the first two or three words of the page, and ask him to go on with the rest. "That is in the middle of the second volume," says he, naming the chapter; "it is Kraszewski's novel 'The World and the Poet.'" "Just so," I answer; "go on, then." And to our great astonishment he goes and reads a whole page, with hardly a slip. Whenever I laid the book aside he stopped; he "read" fluently when I kept my eyes on the text. I turned over a page; still he read well.

Some of the persons who witnessed this experiment thought they had here a demonstration of "second sight," despite the explanations I offered, and which I will state presently.

[1] We shall see later that the explanation of "rapport" given here is in many cases inadequate.

But if it was no "second sight," do we need a better proof of mental suggestion?

Unfortunately, we do! For, first, he "read," though less well, while the book was closed; he needed only to have the opening phrase of a passage given him—therefore it was not thought-transference; neither was it second sight, for without that suggestion of the opening words he could not even read the number of the page, or make out anything whatsoever.

Here is the explanation of the mystery: The youth had shortly before read twice over the novel by Kraszewski already mentioned—had read it as people used to read in Poland in those days, and particularly those 17 years of age. He knew it almost by heart. Evidently he could not recite page after page *verbatim* in the waking state; but the one thing that our experiment proves is, the astonishing *activity of recollection in somnambulism.* And as for the influence of my thought, that is a very simple matter; the subject "saw" better while I was looking in the book, because then I used to correct his little errors. It was these errors that suggested to me the true explanation of the phenomenon; for instead of reading faultily a word in the text, he substituted another word of like meaning, but totally different in form. The regular train of association being thus interrupted, he used to come to a stop if the book was shut, for I could not come to his assistance.

In spite of these failures, I still tried to obtain direct mental suggestion.

1. The subject was required to repeat my gestures, made in an adjoining room, with the door ajar. These experiments yielded no striking result—merely a few coincidences from time to time.

2. With eyes blindfolded, he was required to come to me, passing through several closed rooms.

This experiment was always successful, but it was necessary to inform him in a general way that it was about to be performed. Then, always after a delay of several minutes, he would find me. Quite evidently he was conscious of my presence as soon as he found himself in the same room; but that was no proof of mental action, more particularly because all tests made without previous notice—*ex improviso*—gave only negative results.

3. He was required, by touching my hand, to find out the thought in my mind. Result: little or nothing, though there were a few successes.

I account for a certain number of coincidences as follows:

1. He and I were comrades, living together under the same conditions, and not seldom did it happen that we had the same thoughts simultaneously.

2. The gestures that were repeated at a distance were customary

gestures and attitudes, which are very few and which might easily have been guessed at random. I remember, for instance, having begun the experiments by an order "to raise the right arm." Now this is the first thought that occurs to one who wishes to experiment on mental suggestion, just as when one would prove free will one usually strikes the table with the fist, saying "I can strike or not strike."

As the subject did raise the right arm, but did not carry out the orders that followed, I had the right to judge that simultaneously, though independently, he had the same thought that I had. Be it added that he was notified in advance that he was to perform certain movements mentally ordered by me.

In 1869 I renewed these experiments at Warsaw with an Italian lady said to be "lucid," and whose performances were much talked about. One thing remarkable about her was the almost total insensibility of the pupils of her eyes to light, in the state of general contracture. Having endormed her and applied tests, I was surprised to observe the very great facility with which she recounted her somnambulic dreams; it was indeed a pleasure to hear them. As for "lucidity," or clairvoyance properly so-called, it was very obscure, and not even once did I succeed in arresting the tide of her eloquence by a mental order.

Further on it will be seen that in the state of active somnambulism, when the somnambule talks much of herself, mental suggestion is not possible.

The same year I made also some "spiritist" experiments, which have a bearing upon our subject.

They came about in this way: A sober-minded man one day attended a table-turning seance. Seeing the infatuation and the ready enthusiasm of the company, as they amused themselves with unconsciously pushing the table, "I will believe in the spirits," he said, "if they tell me the forename of my grandfather."

He was himself advanced in years, and was confident that no one in the company knew his grandfather's name.

"It may be that the spirits themselves do not know it," gravely remarked a spiritist who was managing the experiments; "but if you concentrate your thoughts upon the name, which you alone know, they will be able to tell it you."

Some one recited the alphabet, and the knocks on the table when the corresponding letters were pronounced made up the fore-name "Adalbert"—the correct name.

"This is diabolism," said the serious-minded one, and he vowed to himself that never again would he witness the doings of spiritists.

When he told me the story, I was justified in supposing the case to be one of mental suggestion. As I did not believe in the spirits, I

must needs resign myself to this latter hypothesis, or else adopt the hardly probable explanation that it was all mere chance. Nevertheless, considering the complexity of this kind of experiments, and the probability of some sort of illusion, I decided to accept nothing save what should be proved by an experiment to be made by myself under well-known and clearly-defined conditions.

Soon an opportunity was offered to apply the test.

Of the five persons (young women mostly) seated round the table, none, as I was assured by all, knew the name of the grandmother of a certain aged lady, who took no part in the experiment. That name was spelled out. But on investigation I found that one of the girls that turned the table must often have heard the name pronounced; she herself admitted to me that in the course of the seance she had recollected the name, which a few minutes before she believed she had never known.

That sufficed to justify belief in a more or less involuntary influence of her muscles.

I then thought of a purely fictitious name known to myself alone.

The table answered with another name having no resemblance whatever to the one in my mind. I pretended to write a word on a bit of paper. The answer of the table was "louche"—a word that no one had thought of. This showed that the unconscious imagination of the mediums was bound to go astray when it was not guided by some sort of suggestion.

Let us pass to another experiment. Before coming, I had prepared a photograph of one of my friends, putting it in a sealed envelope.

"What is in this envelope? Is it a letter, a bank note, or a photograph?" (I give the question *verbatim*, according to my notes.)

"It is a photograph."

"Of a man or of a woman?"

"A man."

"How old?"

The table gave 23 knocks, which was correct. The believers were delighted; but on reflection, after recalling all the circumstances, I was unable to agree with them.

First, the probability of the correct answer being made was very great—for the first question, 1 to 3; for the second, 1 to 2; as for the third question, the probability there was considerably less, but—I had made a slip which no doubt decided the result. For when the table, after giving 23 knocks, stopped for a moment, I hastily exclaimed "That's it!" But before coming to the twenty-third knock the table had stopped now and then, *and I had said nothing*. The impression left upon my mind was that had the knocking not been stopped by my exclamation, the table almost of a certainty would have kept on knocking.

Next, I noticed that the envelope showed pretty plainly the shape of a photograph card, slightly curved, and manifestly stiffer than a letter or a bank note.

Finally—and this is a point not easy to make plain—I felt distinctly that in that company, and under the conditions given, a photograph of a man was much rather to be expected than the photograph of a woman.

Hence this was a case of suggestion by conjecture, and perhaps a matter of chance.

Here is another instance of apparent success:

I request a lady, not of the mediums' set, to pass to another room, to write some number on a bit of paper, and not to show it to any one.

Upon her return, I ask the table:

"How many figures are there?"

"Two."

"What is the first?" I then name all the numbers, zero included, but the table makes no sign. I begin again:

"Is it *one?*"

"Yes." (It had been agreed with the "spirits" that one knock was to mean *yes*, two knocks *no*.)

"And the second figure?"

The table gave 6 knocks. But we had hardly come to the sixth when the lady exclaimed: "It is astonishing; I wrote 16!"

I must add that she could not decide what number to choose. "Must I write one figure or two?" she asked of me before quitting the room.

"Any number at all," I replied, "one of two or three figures, for instance." Thus the suggestion of *two* figures was given by inadvertence.

We began again, and this time under stringent conditions. I alone knew the number, and I wrote 4; the table guessed 346.

In 1872 a young German lady of high sensibility and delicate constitution, subject to hysterical fainting fits, suggested to me the thought of a new trial. I had made a series of observations upon her pulse changes in various phases of somnambulism. But in her case the psychic phenomena were of little moment, while mental suggestion would not work at all.

I will pass over a multitude of experiments made with persons in the waking state unbeknown to them—making a person, whose back is toward you, turn about when you order him to look at you. These experiments have now and then been successful, but never under stringent conditions. Once, however, the appearances surprised me a good deal. I was in a ballroom. A young woman attracted my attention by her peculiarities of feature; so I often looked toward

her, and fancied that whenever my gaze was fixed upon her for any length of time, she would turn her head and look in the direction of me. Still she could not see me. To verify the phenomenon, I chose a less favorable moment and succeeded. I tried once again, and the success was the same. Then, being in an adjoining room, I said to a friend: "Let us make a curious experiment. Do you see that girl in the corner of the ballroom? I will make her come hither." A minute afterward the young lady rose, entered the room, remained for a moment undecided, cast a look of interrogation upon us, and then went back to the ballroom.

I made her acquaintance a few weeks later. On being tested with the hypnoscope [1] she presented only a slight numbness of the finger. She was rather hard to endorm (15 minutes), and the sleep was very light and was soon over. *No experiment in mental suggestion was successful.*

Was it then an illusion? I believe it was.

Having reflected upon the case, after making the acquaintance of the subject, I interpreted quite differently my prior successes. In the first place, it was nothing surprising that she turned her head while I was looking at her, for having heard of me, she wished to make my acquaintance; and it is even probable that, through a very common illusion, I fancied that I had first noticed her "because of her peculiarities of feature," whereas, in fact, she had for a good while been observing me, and so had, unconsciously, perhaps, given direction first to my attention and then to my experiments.

This incident gave me a disgust for mental suggestion, and many remarkable subjects came under my hands without awakening any desire to test with them the transmission of thought.

I recall another discouraging circumstance:

I went to an "extraordinary" exhibition given by a certain "Vicomte de Caston," who performed feats of memory and præstigiation, improvised verses, read without the aid of the eyes, and divined thoughts. The seance was highly interesting to the psychologist. I say nothing of tricks of the common sort; albeit here, I am free to say, is a study that I heartily commend to every psychologist who is curious about hypnotism in general and mental suggestion in particular. Sleight-of-hand is the result of an ingenious application of the psychology of attention,[2] involuntary associations, illusion, and reflex movements, rather than of psychic power. In hypnotism

[1] This is the name I have given to a peculiarly shaped magnet, which, applied to a finger, serves to show one's hypnotic sensibility. With few exceptions, this instrument always gives positive results, and it is very convenient for use, for its application lasts only two minutes. (See Appendix I.)

[2] See the remarkable work of Ribot bearing that title (Humboldt Library, No. 112). —*Translator.*

the great præstigiator is Hartmann's Unconscious: if one is not to be its dupe, one must be "up to its tricks."

But among the performances of this "vicomte" the thing worthy of mention here was a series of tricks grounded solely on *the association of ideas.*[1] We know how easy it is, by a very simple ruse, to make a person select a given card from among many. You have only to exhibit before his eyes the cards of the pack, one after another, rapidly, but in such a way that only one shall be fully and distinctly visible. You thus trick the subject's vision, and he selects the suggested card as a matter of course. Our psychologic præstigiator had developed this method, applying it to operations purely mental. Having in readiness a certain number of envelopes, sealed and containing a word written beforehand, such as "rose," "diamond," "negro," he opened a lively conversation with the audience. Discoursing *de omnibus rebus et quibusdam aliis*, he would stop just at the moment when the most direct and the most inevitable association was with one of the predetermined ideas. Then by a clever detour he came round again to the same association, *which he never expressed*, and suddenly asked a person he deemed to be absorbed in the performance, to think of some object.

The object thought of was always the one suggested.

All he had to do now was to ask to which of the three kingdoms, mineral, vegetal, or animal, the object belonged, to insure success, and to prove to the person interested that his thought had been written down by itself in a sealed letter.

As the experiment just described is but a conscious utilization of a mental process that is daily and hourly repeated in ordinary life, it follows that in very many cases the *psychic atmosphere* of a company suffices to account for unexpected coincidences of thought between the experimenter and his subjects—coincidences all the more surprising the less one knows about the unconscious mechanism of these suggestions, *mental* suggestions, if you please, though they have nothing to do with thought-transference. Ever since that time I have held that in a successful experiment in mental suggestion there are always *two* questions to be settled. The question, How did the subject divine the thought? is but the second; while the first is, How came the experimenter to choose one thought rather than another? We can judge of the scientific value of an experiment only according to the intimate relation between these two processes.

Whenever several persons hold a conversation for any length of time, there arises between their minds a reciprocal enchainment. A clever observer has then but to isolate himself from this involuntary mechanism and to grasp it mentally in a general view, and then

[1] See "Diseases of Memory," by Ribot, (Humboldt Library, No. 46).—*Translator.*

sometimes he can *foresee* the object that some moments later will occupy the attention of the company. It is this same mechanism that often causes two persons in a company to express the same thought or to raise the same question. The better one knows those about him, the greater his success in this psychic "clairvoyance." I remember how once, being secretary of a society, the object of which was the publication of an encyclopædia of the sciences, I wrote in advance the notes of one of our meetings. The question before the society was whether theology should be reckoned among the sciences that were to be treated. There were two priests on the committee. Knowing the members and their views, I risked the experiment. The "minutes" were written out; they gave an account of the general discussion, and closed with this resolution: "Resolved, that theology ought not to be treated, save as constituting a part of the history of religions." I had to change only a few words in order to submit the minutes to the members for approval.

Of course, one cannot be so good a prophet unless he is in some degree an accomplice; but one is always an accomplice when one orders the carrying out of a thought that comes to us mechanically. For instance, you are a frequent visitor at a house. You do not recollect the fact that at your last visit the conversation was about colonial policy, and that immediately after it was over a lady sat down at the piano. The talk is now again about colonial policy, and the thought occurs to you to make an experiment in mental suggestion. So you order (mentally) the lady to go to the piano—and she goes. You are amazed at your success—all the more because you see no connection whatever between colonial policy and a piece of piano music, and because your chum assures you in all sincerity that in some quite inexplicable way the idea came suddenly to him to take a seat at the piano.

We may utilize this unconscious process with deliberate purpose: My friend P., a man no less absent-minded than he is keen of intellect, was playing chess in a neighboring room. Others of us were talking near the door. I had made the remark that it was my friend's habit, when he paid closest attention to the game, to whistle an air from "Madame Angot." I was about to accompany him by beating time on the table. But this time he whistled something else—the march from "Le Prophète."

"Listen," said I to my associates; "we are going to play a trick upon P. We will mentally order him to pass from 'Le Prophète' to 'La Fille de Madame Angot.'"

First I began to drum the march; then, profiting by some notes common to both, I passed quickly to the quicker and more *staccato* measure of my friend's favorite air. P., on his part also suddenly changed the air and began to whistle "Madame Angot."

Every one burst out laughing. My friend was too much absorbed in a check to the queen to notice anything.

"Let us begin again," said I, "and go back to 'Le Prophète.'" And straightway we had Meyerbeer once more with a special fugue.

My friend knew that he had whistled something, but that was all he knew.

One who knows a person's habits can sometimes imitate mental suggestion, even without any suggestive impression.

In the Medical Faculty of X., we had a professor of philosophy, who, in giving his lectures used to look first to the right, then to the middle of the room, then to the left, again to the right, and so on, with the regularity of a pendulum. In this little habit there was nothing offensive to any one, and it had passed unnoticed. One day he was proving to us the psychic liberty of man.

"You will soon see his freedom of will," said I in pleasantry to my fellow students. So extending a finger, I began to give orders for the movements his head was to make to the right, the middle, the left.

Do not think that this anecdote has no bearing upon our subject. Of course, the thing was but a piece of pleasantry; but had it been taken seriously it would have been a deception. Now, in hypnotism, physiologists are liable to just such deceptions, involuntarily, if while understanding well how to observe external facts, they do not know how to observe their own selves. Here is an instance of this from my own experience: it comes fully within the class of apparent suggestions.

I was treating by hypnotism an elderly lady suffering from chronic arthritic rheumatism. I put her asleep very readily, and absolute repose of half an hour (*aideic*[1] state) always sufficed to calm her nerves, and to improve her natural sleep, at least for a few days. There was no means of producing somnambulism, properly so-called, or of making the subject talk (*polyideic*[1] state), so I left her, and occupied myself with turning over the leaves of a book, and awaiting the time of her awaking. One day I thought I should awaken her by a mental order. "Awake," said I to her mentally, and at once there were contractions of the face muscles; the eyes opened, and she was awake.

Some days afterward I tried to make her perform certain movements, but in vain; but I succeeded in awakening the subject as before, though not so promptly. Still, it was a surprise. But why did she awake, and yet prove insensible to other suggestions?

The reason was this: Here were two habitudes that had passed unnoticed. Continuing the treatment for several weeks, I had fallen into the habit of awakening her just half an hour after sleep had

[1] Aideic (Greek, *a*, privative; *idea*, idea, thought), without thoughts. Polyideic (Greek, *polys*, pl. *polloi*, much, many; *idea*, thought), with many thoughts. Monoideic (Greek, *monos*, single; *idea*, thought), with one thought.—*Translator.*

become manifest. I did not look at my watch, but went always at the fixed time; and as that was one hour before dinner, my stomach took the place of my watch perfectly.

The patient too had acquired the habit of waking almost precisely on the minute—a phenomenon familiar to magnetizers. This does not happen in every case, but it does happen very often.

This suspicion occurring to me, I resolved to find out whether it was correct. I readily found

1. That I was unable to awaken her "mentally" 10, 15, or 20 minutes after she was sound asleep.

2. That she always awoke of herself after 30 or 35 minutes, without any mental suggestion.

Thus we were in just the condition of our anecdote, except that in the one case the cause of the coincidence was known from the first, in the other it was not.

In 1881 I attended, in Lemberg, the magnetic seances given in that city by Donato. Among his performances was one which, though not presented as an instance of mental suggestion, nevertheless wore all the appearances of one. Miss Lucile, who was blindfolded, remained upon the stage, seated, while Donato went among the audience and invited persons to name to him, in a whisper, a certain number of acts for the somnambule to perform afterward. For instance, to fan herself with Mrs. N's fan; to spread Mr. X's opera hat and put it on his head; to take Mrs. Y's bracelet and put it on the arm of Miss Z, and so on. It is to be remembered that the choice of acts to be done is very restricted, the same thing pretty nearly all the time, yet there was no trickery; the *psychic atmosphere* played its own part.

Donato, having received the requests that were made, led Miss Lucile toward the audience, and without speaking a word, solely with the aid of gestures made at the distance of one or two paces from her, then nearer, he conducted the "medium" to the persons in question, and she performed perfectly every act that had been requested.

This experiment made a deep impression, for it was evident that there was neither any understanding with the subject nor any collusion with the audience.

How was Miss Lucile able to perform these interesting feats?

"By *magnetic education*" was the magnetizer's answer. It was vague, and yet true.

There exists in magnetism a phenomenon little studied by hypnotizers—that of *magnetic attraction*, so-called. It is enough to bring the hand near the arm of the endormed subject: at once that arm goes out in the direction of the hand and follows all its movements. Though the magnet produces the same phenomenon, one must not suffer himself to be deceived by the analogy. This attraction has

nothing in common with the attraction of iron by the magnet; it is not of a physical kind, but of the reflex order.

But that is a distinct question, which we need not touch at present. The important point, the one that has to do with the matter in hand, is that this faculty, possessed by very many somnambules, may be cultivated and improved by *magnetic education*. Little by little the subject becomes sensible to various attractions, and if to the automatic attractions there be added quick understanding of gestures, then the subject possesses everything that is needed for a marvelously perfect simulation of thought-transference.

At first the subject is influenced only from anear, and can understand only simple movements; later he grows accustomed to his magnetizer's ways, comprehends his inchoate gestures, and an automatic association is formed between the almost unnoticeable directions of the experimenter and certain reflex, or even voluntary, movements of the subject.

Thus was Miss Lucile able to execute the unspoken orders of Donato.

There is another and much simpler way of simulating mental suggestion. Donato himself has shown that by making certain motions with his fingers at Miss Lucile's ear, he could produce a hyperacusia[1] sufficient to enable the subject to hear words spoken so low and with lip-movements so slight that even persons on the watch for them and observing attentively were unable to hear anything. I have repeated this experiment many a time, in one case—to mention no others—with a peasant woman of Zakopane in Galicia, who, though her ears were plugged and her head wrapt thrice around with a coarse thick kerchief, repeated words spoken as low as possible by me at the distance of 13 feet.

Plainly with such a degree of hyperæsthesia the subject can:

1. Hear direct what is spoken in the ear of the magnetizer;

Or, 2, hear what later he whispers into her ear, unheard by the bystanders.

Donato kindly held for my behoof a private seance, at which I had an opportunity once more to experiment on mental suggestion. The magnetizer himself expressed some doubts upon that head. The phenomenon he believed possible, and he had once demonstrated it in the presence of Mr. Arkasof; but according to him the experiment is but seldom successful—how, no one knows; in most cases it miscarries—why, no one can tell.

We made the attempt, nevertheless.

Miss Lucile stood with her back toward us; I was on the right of the magnetizer, between 6 and 7 feet from the subject. The latter

[1] Hyperacusia: Greek, *hyper*, over; *akoue*, hearing. A super-sensibility of the sense of hearing.—*Translator*.

was to *extend the left arm.* After a minute there were some slight movements of that arm, or rather of the whole body—movements that may have been produced by the subject's fatigue, and may have had no relation to the intentions of the magnetizer. This was readily admitted by Donato. "I should be more sure of a result," said he to me, "if you would allow me to act by gestures." But that was not the question; undoubtedly, he could, acting by attraction, cause the the arm to be extended.

Other attempts had no better result, whether it was I that gave the order after endorming the subject, or whether it was Donato himself. I simply proved again what I had already proved with one of my first subjects, to wit: the subject's power of recognizing the person that touches her on the back (through the clothing). When Donato endormed her, a touch from me caused her pain; the contrary was the case when I myself magnetized her, but she always bore more easily the touch of her customary magnetizer.

Care was taken that the subject should not be able to tell who touched her, except from the mere act of simple, slight contact.

This phenomenon I have since verified in nearly all highly-sensitive subjects, when *magnetized* (*not* hypnotized), and so I have been obliged to postulate an individual physical action not found in Braid's hypnotism.

This physical action is a matter of no slight importance in the problem of mental suggestion, as will be seen later, but evidently the one does not imply the other.

Notwithstanding this evolution of my views, I was still far from believing in thought-transference. On the contrary, the foregoing attempts discouraged me, bringing to light the full complexity of the question and all the causes of error.

One thing I had learned, to wit: that a skillful magnetizer who has a suitably trained subject, can imitate mental suggestion perfectly, or may himself be duped by unconscious associations. Witnesses in relating the performance, transfigure it, embellish it involuntarily, in virtue of the psychic faculty—of great value in art, but highly dangerous in science—which has been called "complementary imagination."[1]

By omitting details that seem insignificant, and magnifying others that seem essential to the understanding of the situation, one makes up in his own mind an experimental "demonstration" that in reality demonstrates nothing but one's own personal enthusiasm. If in narrating the facts for the first time one adapts them just a little "*in usum Delphini*,"[2] one will recount them the second time *pretty nearly*

[1] *Fantaisie complémentaire.*

[2] A famous annotated edition of the Latin classics was prepared in the reign of Louis XIV., "for the Dauphin's use"—*in usum Delphini.*—*Translator.*

as at the first, and the third *pretty nearly* as at the second; slight modifications then go on accumulating and little details drop out. Thus, persons little used to strict scientific method in the end will, in all sincerity, tell of things that never were. A scientific man will not go so far as this, yet he may easily permit himself to be fascinated by a novel and unexpected impression received under conditions that either cannot be, or that at least have not been, ascertained with precision. That is enough to lead to an erroneous *interpretation*, which may go so far as to assert the existence of a new phenomenon that does not exist at all. Lest I should be accused of exaggeration I give an example:

Mr. Hughes, inventor of the microphone, the printing telegraph, etc., a noted physicist and thinker, believed it to be demonstrated at the beginning of his researches that the microphone *increases* the intensity of sounds. That was an error of interpretation, caused by certain illusive effects. No microphone has ever amplified the intensity of *speech*, or of *sounds* in general; on the contrary there is always a notable reduction of the intensity. How comes the error, then? From the failure to distinguish between the *sounds* and the mechanical vibrations accompanying them. The microphone makes audible the tread of a fly over a thin planchette, but not because it amplifies the *sound*—which, indeed, is imperceptible directly—but because it *transforms* into sounds the mechanical vibrations of the fly's tread. Place near the planchette a watch that makes a far louder sound, and you will hear nothing; but set it upon the planchette of the microphone, and you will hear the ticking through the telephone a great deal better than you can directly, because in the latter case the mechanical vibrations are transformed into sounds, and these are added to the real sounds. Now, this error of interpretation has circulated so widely that even to-day you will find it asserted in works on physics that sounds are amplified by the microphone—in other words, a fact is said to exist that has no existence at all.

The case is often much the same with regard to mental suggestion. It is not the evidence for the naked fact that is at fault, but the interpretation of the fact—the determination of the causal relation between two phenomena that in themselves are verified easily enough. The thought of one brain is succeeded by a like thought of another like brain: is the case here like that when two telephones influence each other by the aid of undulatory currents? or are the conditions like those of the two watches supposed by Leibnitz, which, while indicating the same hour, were mutually independent? That is the question. And it must be added that between these two extreme situations there is plenty of room for an intermediate state of some complexity; for while independent in their mechanism, the two watches may be imperceptibly regulated electrically or pneumatically. Have the physicians

who like Barrier, Teste, Bertrand, Charpignon, Garcin, Despine, *et al.*, vouch for us the reality of thought transference—have they seen an actual transmission? They have seen only two watches that *sometimes* indicate the same hour. I was therefore justified in regarding their testimony as insufficient, and that for still another reason:

In order to judge aright of such a fact as this, one must of necessity have in mind the *suggestion theory* of hypnotism; one must ever remember that all hypnotic phenomena whatever may be produced by imagination alone, by *ideoplasty*.[1] Consequently, to make out a case of somnambulism produced from a distance, for example, it is not enough simply to verify the fact; we must furthermore have absolute certitude that it has not been possible for the subject by a combination of the circumstances or by the behavior of the person whose business is to observe him, to *presume* what the experiment is to be. Further, this presumption itself *may be unconscious even while it brings about the desired result.* On this point my hypnotic studies leave no doubt. In fact, even when the subject has anticipated nothing, when he declares that he has suspected nothing, one is not free from uncertainties. Hence, notwithstanding all that has been published by the priest Faria, by Hénin, Cuvillier, Bertrand, Braid, Durand, Gros, Morin, Szokalski, and Liébeault, the theory of suggestion was really not known and recognized till the publication of Dr. Bernheim's ingenious work. At one time the action of "magnetic currents" in space was found to be comprehensible, but it was held to be improbable that somnambulism might be produced by means of a letter (not magnetized) fixing the experiment for a given hour. The subject fell asleep a few minutes after a concentration of will at a distance, therefore it was the thought of the magnetizer and the "magnetic fluid," its agent, that produced the somnambulism; *post hoc, ergo propter hoc.*

For a long time these doubts seemed to me sufficient to withhold me from new experiments. But one always returns to his first love.

While giving at the University of Lemberg (1875–'81) a course of lectures on physiological psychology, I studied the different questions of hypnotism a good deal. Many of my students willingly offered themselves for all sorts of researches, and then it was that I began to see my way a little better in this mysterious region. One day I brought together six of my best subjects in a hall of the Polytechnic School, from which every ray of light was excluded, in order to test the alleged discoveries of Baron Reichenbach.[2] We remained three

[1] Ochorowicz, *Sur l'idéoplastie: classification des faits; et sur la théorie de l'idéoplastie* (*Comptes rendus de la Société de biologie*). Ideoplasty (Greek, *idea*, idea, mental image; *plattein* or *plassein*, to shape, whence *plastes*, modeler), imagination, or the power of conceiving, or forming, mental images. See Appendices II., III.—*Translator.*

[2] Reichenbach asserted that the "influence" of a magnetizer upon his subject is manifested in a dark chamber by luminous rays emanating from him.—*Translator.*

hours in absolute darkness, yet were unable to verify any of the statements of the German chemist. But to make amends, we discovered a new fact of considerable interest, namely, that certain hypnotizable subjects see far more distinctly the phosphorescence of an electric machine than do other persons. Threads of light, quite invisible to the rest of us, and forming a prolongation of the visible rays, were described perfectly by some of the subjects, and were objectively verified in divers ways.

I chose two of these subjects for an experiment in mental suggestion. The first, a youth of good stature and remarkably muscular, in good health, but highly sensitive to hypnotism (hypnoscope showed: irritation, anæsthesis, contracture) presented this peculiarity, that it was impossible to produce in him an hallucination or any word-suggestion whatever. Endormed by fixing the gaze, or by other equivalent means, he showed *a general contracture* and, psychicaliy, a state of complete *aideism* (tetanic aideia). To make him talk, it was necessary to free the speech muscles, which were all contractured; and once a reply was obtained, he did not fall asleep any more; a certain dizziness and a general contracture alone remained. It was possible to awaken one hemisphere alone, and one-half of the body, but *somnambulism* could not be produced. He passed straight from the "lethargic" state to waking; but in waking, as well as in the lethargy, it was possible to produce by localized passes, insensibility, hyperæsthesia, attraction, catalepsy and contractures, but hallucination never. So pronounced was the neuromuscular hyperæsthesia, that to produce a local contraction or contracture one had only to bring near to any part of his body, divested of clothing, a finger, a magnet, or to project a ray of light, or even to look fixedly upon it.

If I endeavored to influence him mentally by ordering a movement, that movement was not performed, but the member on which I looked was seized with contracture. If instead of acting by look I acted by gestures, there was an exceedingly strong attraction of the whole body, and he performed all the acts indicated by the attractions, till a general contracture obliged him to fall rigid or to stand motionless. The rigidity had then to be removed by gentle massage in order to continue the experiment.

This special sensibility was developed little by little. The attraction did not manifest itself till the fifth magnetization. (All these experiments were reported to the Medical Society of Lemberg in 1881.) It was proven to my satisfaction that he was capable of being influenced by looks—though the experiments were not always successful when made *extempore;* but it was certain, at the same time, that mental suggestion by itself alone was always without result; there was no trace of effect. When *hypnotized*, he obeyed every one; when *magnetized*, he followed only his magnetizer; the latter alone could awaken

him, or cause the contracture to disappear, but always by massage, passes, gestures, by blowing on the subject, not by a mental order. Once or twice only did I succeed, in the state of momentary stupor of the brain prior to the awaking, in transmitting to him some *physical sensations*—as a painful puncture, a bitter taste—but even then there was uncertainty as to interpretation, and I could not guarantee the value of a few successes.

My other subject was also a young man, tall of stature, but not strong ; highly intelligent, rather anæmic and consumptive. He was very sensitive, even too sensitive, to all sorts of impulsions (hypnoscope showed analgesia, instantaneous contracture of the whole arm). The application of the hypnoscope at the pit of the stomach produced in him a series of peculiar phenomena—sensations, contortions, sharp long-drawn cries, and rotary movements of the arms, the head, and the whole body. He was remarkable also for somnambulic and suggestional dreams of all the senses.

First Experiment.—The subject, being in somnambulism (polyideic state), counts from 1 to 50. His counting was to be interrupted by a mental order *from a distance.* Result : a few coincidences, but in most cases the paralysis came too soon—it preceded the mental order : consequently it had to be regarded as produced by ideoplasty.

Second Experiment.—I touch the nape of the neck with my finger, and mentally order him to arise and go sit on a bed. The subject rises partly, slips to the floor, sits down, bows, kneels. One of the company, B, an engineer, says it was he that mentally gave him the order to kneel. (Probably the slight downward pressure of my finger suggested to the subject the idea of sitting on the floor, and then the lowliness of his position produced in his mind the image of an attitude lowly *par excellence* and more convenient—that of kneeling ; while at the same time, and through a like association, B got the idea of ordering that posture).

Third Experiment.—No touch and no gesture. The whole company think on making him *raise the right leg.*

He remains motionless, but says he wishes to *dance.* (The resemblance does not suffice to justify a conclusion.)

Fourth Experiment.—I alone give the mental order. I do not touch the subject, but I use gestures, and direct my looks toward the member in question. The subject is blindfolded. I stand in front of him at distances of 2, 3, 4 and 6 paces, respectively.

He performs various motions ; rises, walks to the right, to the left, forward, backward (he retreats slowly and with difficulty), kneels, sits. I order him to extend the right arm—and he raises the left, that being the only act in this experiment that failed ; at that time I was distant from the subject six paces. When repeated, *without gestures,* these experiments gave no positive result. Repeated with gestures,

but *without any special concentration of the will*, they gave nearly the same positive result as at first.

Fifth Experiment (a few days later).—The subject being in somnambulism, his eyes bandaged, his ears plugged, I stand in front of him at a distance of from thirteen to sixteen feet, and make gestures of attraction and repulsion.

For more than an hour all the tests of this fifth experiment were successful. The principal one was to determine whether the subject really had a sense of my presence. I therefore hid in remote corners, while I attracted him toward me. I took all possible care to make no noise. I changed my foot-gear; another person imitated my tread. I tried to lead the subject astray by speech, etc.; he followed me everywhere and found me always. In coming toward me he *sniffed like a hunting dog* (of all the persons present I was the only smoker, and my clothing was impregnated by the odor of tobacco).

Result: the subject was guided:

1. By an exceptional sensibility of the whole surface of his body for motions of the air (gestures at a distance);

2. By an exceptional sensibility for warmth (he felt the warmth of my hand at a distance of thirty inches);

3. By an exaltation of the sense of smell; but not at all by mental suggestion.

Sixth Experiment (some days afterward).—The sleep not perfect; he partly recollects after awaking (this, perhaps, because of the emotions of the day). Attraction often lacking.

One of my pupils, P., deceives the subject, who confounds him with me. The movements ordered are executed badly. The subject improvises, giving his dreaming fancy a free rein. He performs movements that no one thought of, while having the appearance of being under an influence. General result strictly negative.

Here is another negative experiment, performed on an hysterical young woman of marked sensibility. (Hypnoscope showed paralysis, contracture, and total anæsthesia of the finger.) There were two magnetizers, Dr. B. and myself. We each touch her on the head with a finger, ordering her to seize some object. The only result is that she falls asleep, but after a peculiar fashion, for the left half of her body is in rapport with me, the right with Dr. B. She hears me only through the left ear, and Dr. B. only through the right. So, too, with regard to attraction. If I touch the right arm, she has no sensation; it is the same if I touch her with any object, a stick, for instance. Looks have no effect, neither has purely mental suggestion.

Here are some experiments upon "willing."

We are in the Count D.'s *salon*. One of the ladies tells me how she several times has succeeded in suggesting to her friend one act or

another by placing her hands upon her shoulders. I make a few experiments which are successful, or nearly so. But in this sort of performances mental suggestion plays no part. Having studied the unconscious muscular movements that cause a table to tip, or a pendulum to sway, as explained by Chevreul, I knew what to think of these phenomena. These involuntary movements suffice to suggest directions to the subject, who is thinking of nothing and whose body is in unstable equilibrium. Sometimes he *divines* the rest, that is, even acts that cannot be indicated directly.

Yet one of these experiments surprised me. The Prince C. is *sitting* in an arm-chair—consequently is in a stable position. Two ladies kneel before him and form a circle by joining hands with him. The order is for him to *cross his legs and to dangle the right.* The order was carried out after a few minutes. In this case the explanation is complex. Involuntary movement of the legs is difficult when the subject is in a fixed position, with hands held, as in this instance. But first, just because of that position, the legs alone (and the head) were free, and hence it is not surprising that after some minutes of immobility he should have felt the need of moving his legs, and the only thing he could do, in view of the position of the ladies, was to cross them. Then, if only to verify the experiment, the eyes of the ladies were sure to turn every moment to the right foot of the Prince, who more or less automatically directed his attention to that point. The direction of attention toward a given point of the body always produces a tendency to movement, and the only convenient movement was the one he performed.

I must add that before this he made several movements *of the head*, which were disregarded as "unimportant;" but had one of these movements been selected, we should not have waited for the others, but should have had the same right to claim a success.

During the same evening I made still another experiment simulating will-action at a distance. Having noticed the sensibility of the Countess D. (hypnoscopic experiment: heat, numbness), I stand facing her and fix my gaze upon her for two or three minutes; then I move away, walking backward, and she follows me; I quicken my pace, still backward, and despite the laughter of the company, and though she made some opposition, she is obliged to follow. This experiment, one now quite familiar through Donato's performances, seems to prove a physical action of the will and of the eye. That is not so, however. The fixing of the gaze, expectant attention, and emotion produce a sort of fascination that may be regarded as an *intermittent monoideism.* Without losing consciousness and will completely, the predisposed subject undergoes, from moment to moment, the inhibitory influence of *his own mind;* he is not paralyzed, but is subject to the *visual suggestions* that dominate his will.

Another experience in "willing" tried by the two ladies with the Count P. as subject was unsuccessful, and yet he was a sensitive subject (hypnoscopic experiment: prickling, heaviness, anæsthesia). I drove a pin into his finger, which had been locally "insensibilized" without hypnotization. This proves that the success of this sort of experiments is not always in proportion to the sensibility of the subject. We shall see further on what are the precise relations between *hypnotism* and *Cumberlandism*. I modified these tests in experimenting upon other persons.

Mrs. Sch., robust, but anæmic, subject from time to time (under the influence of emotions) to cataleptoid hysteric fits (hypnoscopic experiment: anæsthesia, localized contracture), is, while in the standing posture, put in the state of fascination by fixing the gaze. Mental order: *To pull me by the beard.* She slowly raises her hand in the direction of my beard, but does not touch it.

Mrs. A., weak, thin, nervous, but in fair health (hypnoscopic experiment: no result). Mental order: *To embrace Mr. S.* She goes in the direction of that gentleman and says: "I am to embrace some one."

Miss R., lymphatic, but in perfectly good health, with little sensibility (hypnoscopic experiment: prickling, heaviness). Mental order (with touch of the hand on the occiput):

1. *To go to the piano.* After a couple of minutes' hesitation, "I must play," said she.

2. *To embrace Miss E.* After a minute's silence, she says: "I am to embrace some one. It is you, Marie. No; it is you, Edvige."

3. *To guess whether I am thinking of an affirmation or of a negation.* She exclaims almost immediately, "You are thinking yes." The contrary was the fact.

Barring the last experiment, which might be regarded as the result of a mere erroneous conjecture, all the rest seem to indicate a real action. But they were not performed under faultless conditions; the subjects were not blindfolded, and the rest of the company, being in the secret, may have influenced them by their attitude. At all events, I remember distinctly that my individual impression derived from these experiments was not decisive. The first two, though more surprising than the last, because of the nature of the injunctions, which could not be easily conjectured, were not carried out fully. The others, in giving which I touched the subject, left room for doubt, as is always the case when that method is employed; and, besides, the acts enjoined on the subject may have been selected under the influence of the *psychic atmosphere*. I remember, for instance, that in the first part of the evening on which the last three experiments were made, Miss R. was asked to play a piece on the piano and refused. Little wonder, then, that when later she had to execute a suggestion, the same act came to her mind.

Then, the number of acts from which a choice has to be made on such occasions is very small. Indeed, in a decorous company what is there for you to bid a young woman do but to go to the piano, to embrace her sister, or the like? And if the order is merely to seize some object or to go to a place indicated, the touch of the hand and its involuntary pressures guide the subject very well indeed. I mention these petty details to show how needful it is to be circumspect and attentive in researches of this kind.

It was about this time that, having acquired a certain acquaintance with hypnotism, I resolved to apply it to the treatment of diseases. The result was surprising, and I saw not only that the assertions of magnetizers might be true, but also that a rational and methodical application would probably lead to the establishment of facts more surprising still. To-day we are beginning to take steps in that direction, and certainly it is time that, having demoralized a number of hysteric subjects, we should restore them to health by the same process.

Being absorbed in therapeutic study, I had neglected the problem of mental suggestion as apparently of no practical value; and it was only by accident that I had occasion to observe a few more or less unexpected phenomena connected with it. For instance, one of my patients could always tell, as soon as I touched her, whether my impressions during the day had been pleasant or disagreeable. She suffered from a complicated disease, which I might be tempted to call chlorotic ganglionic neurosis, and had been for thirty years bed-ridden. She was excessively impressionable, yet was insensible to hypnotism and to metalloscopy (hypnoscopic experiment: no result). An interesting peculiarity was that my hand seemed to her always warm, even when it was of much lower temperature than her body. As my attitude toward her was always the same, I marveled not a little at this faculty of discerning my mental state. But there are a thousand ways of guessing such things, as from the expression of the face, or from the tone of the voice; and there is no need to suppose a direct transmission. True, she could also tell whether before coming to her I had touched any other patient; but she might have inferred that from certain signs of fatigue, or from my coming a little late; perhaps, too, she was aided by olfactory sensations.

Another patient showed a like gift with regard to the persons who were habitually about her. She was hysterical, very easily hypnotizable (hypnoscopic experiment: anæsthesia and contracture of the whole arm), and manifested this aptitude only at the moment of awaking, *i. e.*, in a state intermediate between somnambulism and the waking state. She would then say of her own accord: "Oh! how weary X is of his work!" "Why is Y so worried?" "To-day you have more

hope of curing me, and you are very much pleased. I thank you for that," etc. All this she would say before opening her eyes, and often without a single suggestive word being spoken. Was there a real transmission of states of mind? I did not think there was. The same people were always around her, and she knew them well enough to be able to make these prejudgments. But there were a few strange coincidences.

Finally, a third patient, a Frenchwoman, knowing not a word of Polish, made apt reply (in somnambulism) to an observation made in the latter tongue. There was no analogy between the words. But this thing did not occur again, all further experiments in mental suggestion having failed, so I set the occurrence down to the account of chance. This subject was easily hypnotizable (hypnoscopic experiment: heaviness, anæsthesia and contracture of the whole arm), and often, *in the waking state*, divined the complaint of a stranger by simply touching his hand.

Having heard of many feats of this sort, I decided myself to investigate, so I asked her what disease she found in me?

"None; you are never ill; a slight congestion when you work too hard, but otherwise your health is perfect."

That was the exact truth. As a second test, I took her to one of my patients, a woman whose complex malady, though it presented lesions clearly characterized, still was not easily recognizable from the appearance of the patient. She had formerly had an attack of pneumonia, and there was hepatization of the right lung, chronic inflammation of the larynx, dorsal hyperæsthesia, frequent headache, several defects of circulation, dyspepsia, and intermittent general debility. Despite all this, the patient, thanks to her exceptional constitution, looked well, and no one would, on first seeing her, suspect her case to be so serious.

The somnambule, after touching the patient's hand, named pretty nearly all her maladies. She did not describe the lesions in sufficient detail, but with regard to the symptoms her diagnosis was very accurate. And more accurate still was her capital description of the patient's character and of her bad habits.

"On what do you base your inferences?" I asked. "Do you think that you see the organs that are affected?"

"No," she said; "rather I myself *feel* the symptoms of the disease."

And, in truth, I have seen her suffer and for a moment present certain morbid phenomena of another patient that she examined, but whom I did not know.

Her feeling the symptoms might be explained by *ideoplasty*, but even so, she would have to know them. And here it is that doubt begins. The somnambule did know the symptoms. But she was a very well-informed midwife, possessing a certain amount of medical knowledge

and a good deal of experience: hence she might well have had other guidance than that of a mystic faculty. After all, one or two experiments are not enough. On the other hand, however, I must admit that the somnambule then saw my patient for the first time; that during the whole consultation she kept her eyes half-shut, and did not attempt to examine the patient according to any of the ordinary methods. As for the influence of the imagination in feeling the symptoms, that explanation becomes doubtful from the fact that the somnambule was not *suggestionable* at all, whether in the waking state or in somnambulism. She passed rapidly out of the aideic state into *active polyideism*, the latter resembling the waking state in all respects, save that it presented anæsthesia of the limbs.

I may cite, in connection with the fact here observed, a passage from the report read before the Paris Academy of Medicine, in 1831, by Husson: "We have found a somnambule that told us all the symptoms of the illness of three persons."

Was the case I have described one of mental suggestion? I alone could know the condition of my patient; the somnambule may have read it in my mind.

This hypothesis did not to me seem admissible, for the reason that no voluntary suggestion had been successful; besides, it is better to hold to an explanation of a less extraordinary character—*a transmission of the symptoms of a disease.*

Is *that* possible? I know not. I do not think we can hold with certitude the existence of a faculty whereby we directly *feel* all the peculiarities of another's pathological state; and yet, a Paris physician has assured me that not only does he possess that faculty, but that he never needs any other means of diagnosis.

All that I can testify from my own experience is, that there exists another sort of nervic transmission, more general and less "circumstantiated;"[1] and this, too, for a long time seemed to me untenable and absurd.

It is a popular belief of very ancient standing, that one may *give the pain* he suffers to another person, or even to an animal. Many a case of this kind have I heard of, and many a one more is mentioned in the writings of magnetizers and of a few physicians, but I will tell only of what I myself have seen and experienced. Here are the conclusions I have reached in my own practice:

1. The act of magnetizing, even when it is restricted to imposition of the hands, is much more exhausting than an act mechanically analogous.

2. This exhaustion is more marked when one magnetizes a sick person than when one magnetizes one who is sound.

3. This nervous exhaustion, which manifests itself by certain

[1] *Circonstanciée.*

special characters, is sometimes accompanied by a transmission of pain.

4. The kinds of pain that are most likely to produce this phenomenon are the "fulgurant" pains of the ataxic, rheumatic pains, and dorsal hyperæsthesia.

5. Prolonged contact facilitates this phenomenon, which, though more rarely, is manifested also as a sequel of magnetization without contact.

6. The transmission is rarely definite and immediate. Sometimes, not often, the pain visits the same part of the body, and this occurs particularly when one has to do with several patients, all presenting the same symptoms. But, as a general rule, it attacks the *nodi minoris resistentiæ*, and manifests itself mostly the following morning at awaking.

7. Transmitted pains are always much lighter and of short duration.

8. Besides pains, certain pathological *states*, as congestions, cold in the head, insomnia, etc., may also be transmitted as a consequence of a magnetization. They are easily distinguished from an indisposition of spontaneous origin in the magnetizer himself, by their sudden appearance and disappearance, as also by their superficial character, so to speak. They do not bring with them the other consequences that belong to spontaneous pathological states.

9. The phenomenon is always accompanied by a notable relief to the patient whose disease condition is communicated. One might say that *the nervic equilibrium is established at the expense of another organism that is more in equilibrium.*

Hence, holding as I do that there is a more or less general transmission from the patient to the magnetizer, I cannot deny the possibility of a more explicit and more detailed transmission from the patient to a hypnotizable subject or one made hyperæsthesic by the methods of artificial somnambulism.

Two bodies of unequal temperature tend to equalize their temperature. Two bodies unequally electrized tend to equalize their electricity. Two bodies unequally equilibrated in their nerve functions tend to equilibrate those functions.

Comparison is not demonstration; yet it brings out an analogy, and that helps our ignorance a little.

And as for thought, does not that correspond also to a nerve state? Undoubtedly; nor have I ever denied the theoretic possibility of transmitting a psychic state, any more than I can deny the theoretic possibility of transmitting the human voice across the ocean—more particularly since a certain lesson in circumspectness I once got myself. In October, 1884, I was still fixed in the belief that, because of the radical antagonism existing in the microphone between the sensibility of its constituent parts and distinctness of utterance, we should

never succeed in reproducing speech in a loud voice ; and I held that a multitude of facts and strictly logical arguments justified that conclusion ; yet in October, 1885, I myself invented the *thermomicrophone*, which reproduces speech in a loud voice. So, then, let us repeat the wise remark of Arago, quoted at the beginning of this work, and proceed with our investigation.

Coming to Paris in 1882, I naturally visited everywhere, wherever anything relating to hypnotism was to be seen. One day I witnessed some hypnotic experiments at the house of a physician. After exhibiting all the wonderful feats of an hysterical young woman, duly trained, the physician gave me a surprise in the shape of an exhibition of mental suggestion. The experiment was made in this wise :

The somnambule having received the (verbal) order to go to the end of the room, she went thither, her eyes half shut, with the air of a school-boy that knows his lesson perfectly, then stood still, facing us. Then the doctor fixing on the subject a look of stern command, "mentally" ordered her to come back toward us (we were standing beside her bed). After a few moments of hesitation and impatience, the subject came back to us. The doctor turned to me with a smile of triumph, as though he were to say, "Isn't that astounding?" But the only thing that astonished me in the matter was the honesty of the experimenter, content with so little.

If when he questioned the subject whether she felt any sensation whatever in the legs, and she answered that she did, indeed, feel something, he took that as proof that this something was the result of "mental suggestion." Of course, these experiments could serve only to make me more incredulous.

With regard to "demonstrative" experiments, repeated for the benefit of the curious, I must here lay down a general rule that will, perhaps, seem over-rigorous :

One same experiment in mental suggestion, repeated under the same external circumstances, has no scientific value. When first made, it may possess the value of an isolated fact, but it possesses that value no longer when it is made a second time in the same way, and under the same conditions. Here is an example to show what I mean :

A curved finger may signify many things, or nothing at all. But if you make a somnambule in the state of suggestionable hypnotism believe that a parrot is perched on that curved finger, the next time you have only to hold the curved finger out toward the subject in the same way in order to make her at once see the parrot perched upon it.

This phenomenon is possible in the polyideic state : it is inevitable in monoideism, for then control is out of the question, and the subject does not think, cannot conceive but one single idea, and that idea you

inculcate directly or indirectly. In the case under consideration it is the inseparable *association* that completes the direct sensation.

Suppose the somnambule that comes back to where the doctor and I are standing, was, in the first instance, moved simply by impatience and a wish to return to her couch; or suppose that there was some sort of real action: these alternative suppositions are of no account when the experiment comes to be repeated another day under the same conditions. There is already formed a more or less invincible association between the thought of being at the lower end of the room, the stern look of the doctor, the expectancy expressed by the faces of the lookers-on, and the intention to go to them.

This remark upon the importance of association by contiguity first, and afterward by habit, is very simple, yet it is too often lost sight of. I have, indeed, been astonished to see it disregarded by distinguished physiologists who have not the knack of psychological observation. So general is this disregard that it is become the sole cause of a multitude of entirely erroneous generalizations, which nevertheless are accepted in hypnology as principles.

For example, there is absolutely no essential relation between "open eyes" and catalepsy. Catalepsy can be produced with the eyes of the subject open, or half shut, or entirely closed, or in perfect darkness. But catalepsy may be induced by any sudden, lively impression that takes the subject by surprise. Suppose the subject on lifting his eyes is met by a bright flash of light, contrived beforehand by the "impressioner." He suffers the nerve-shock of this impression and instantly falls into the hypnotic state of catalepsy, and has not time even to close the eyes. That is enough; there is formed an ideorganic[1] association between a sudden opening of the eyelids and the organic state of catalepsy. The brain being momentarily paralyzed, other ideas there are none, and consequently they cannot interfere with the forming of this association.

Lower the eyelids and the limbs grow relaxed: by suppressing the first term of the association you cause the other to disappear. If on the strength of this experiment you announce as an axiom that "catalepsy is produced by opening the eyes," or that "the subject in catalepsy keeps the eyes wide open," you make a statement that has no more value than if you were to say that "in catalepsy the subject keeps the eyes always closed," on the strength of another individual habit as easily producible.

To verify the cataleptic state the usual way is to raise the arm of the subject: if it falls, he is no longer cataleptic, else the arm would have retained the position you gave it.

Once I tried to produce catalepsy by a mental order, after ascer-

[1] Ideorganic (idea -|- organ) association; an association between a thought in the mind and the action of a bodily organ —*Translator.*

taining that the muscles were perfectly lax. Catalepsy appeared: the arm stood out from the trunk. I removed the catalepsy, to begin again; the arm fell. I mentally ordered the catalepsy to return; again it appeared; and so on. Had I any ground to infer that there was real mental action in this case? Not at all! Here is the true explanation of the phenomenon:

When experimenting for the first time upon the subject in question, I had produced catalepsy in the arm by lifting it with one hand while with the other hand I made a few passes (gentle massage) from above downward. It took several minutes to produce the lightness and mechanical flexibility of the member which constitute catalepsy.[1] But by repeating often I reached this result much more speedily; one pass along the arm was enough.

After this experiment I concluded that not even the one pass was necessary; there had been formed an ideorganic association between the act of lifting the arm and the cataleptic state. The one called forth the other; hence my mental suggestion played no part, and *I produced the catalepsy while trying to find out whether it existed.*

But, you will say, the same movement of the arm a moment ago showed a complete relaxation of the muscles; how, then, is it that the same movement suggests at one time simple paralysis (lethargy), and at another time the cataleptic state?

The reason is that the movement *is not the same.* We lift the arm in one way to make it fall, and in another way when we wish to see if it will not stand rigid. A slight difference in our state of mind suffices to give to our muscles and to our fingers a difference of motion and of touch that in hypnotism is quite sufficient to reproduce the organic association of catalepsy in one case, and not to reproduce it in another.

Our touch is of one kind when it is entirely without purpose, it is another thing when we *wish* to produce an effect; of one kind when we *have no belief* in its efficacy, of another when we have unlimited confidence. "Will and believe"—but you will then find phenomena that do not exist.

The unconscious, as I have said, is the great præstigiator in hypnotism, and many a trick it plays upon us. But, I must add, it rarely does so dishonestly. It is, on the other hand, perfectly docile, and never was animal more easily trained than it is. The misfortune is that we train it all unconsciously and without appearing to do so.

Then it is that the unconscious of each of us disports itself in playing tricks on each other one—and upon ourselves.

In the two instances just cited, I postulate *a really active intermediary*—a bright flash of light and a gentle massage—but these are not essential; the unconscious can divine your thoughts without them,

[1] *Cette légèreté et flexibilité mécanique du membre qui constitue la catalepsie.*

provided you remain steadfast in your wish. You lift the subject's arm, and it falls; try again, and the subject will perhaps hesitate, and the arm will drop to his side less quickly; keep on, and probably the unconscious will say to itself: "Evidently they want me to maintain the posture they give to the arm. I am willing." And you will get your "cataleptic state" without any accessory manipulation.

It is in this way that certain magnetizers have found a number of "polarities" in the human body. I have seen their experiments, which are quite convincing: the thumb attracts, the little finger repels, and so on. The unconscious having learned its lesson, no longer contradicts itself. Yet, if you use a little entreaty—albeit, without any words—you will easily obtain the opposite result, and you will get any polarity whatsoever, according to whatever fanciful plan you may lay out in advance. Three seances are enough *to produce a habit of re-action.*

(Of course, these remarks do not settle the question of polarity in general. Upon that question I do not mean even to touch. I merely say that it is possible to inculcate into the subject an imaginary polarity.)

Even when you experiment without contact, even when you act upon a sleeping person, *who, however, has already been magnetized by you,* you must be on your guard against unconscious habitudes.

The possibility of producing somnambulism in a person that is in natural sleep, and who has no suspicion of your presence, is often cited as proof of *fluidic action,* or mental action at a distance. But in most cases this, too, is an illusion, and when the experiment is successful, proves one thing only, to wit, *the force of ideorganic associations.*

You have the habit—perhaps quite unconscious—of disturbing the air in front of the subject's face, when you make passes in a peculiar way of your own. The subject, or rather his unconscious, divines your presence, feels you are there, obeys you; the association of these impressions with the organic state of somnambulism produces the somnambulic state. Try some *new* method—one that would have been equally effectual in the waking state, because of the conscious suggestion—and *you will obtain no result.*

In purposely employing the principle of association, we come upon curious applications of it. You choose whatever link of association you please, and connect that with one, two, three, four or more similar links, be they ideas, sensations, acts, states or whatever you will. It is not necessary that there be any logical relation at all between the first link and the ones that follow.

I once had as a patient an insane woman, fully bent upon suicide, but who always very carefully planned in advance the carrying out of her projects. In the normal state she never would tell me about them, and by degrees she became mistrustful even in somnambulism. The

monoideic state, which is always characterized by absolute submission, it was almost impossible to produce, and the most trivial question made her pass straight from the *aideic* state to *active polyideism*, in which she regained her independence. Still it was necessary to learn her secret in order to prevent mischief. To this end I contrived the following ruse. Having been in the habit of sitting on the right whenever I talked with her, one day I sat to the left of her, and taking advantage of a favorable moment—a sort of visional delirium akin to monoideism—I changed my voice slightly, and made answer to her raving, taking care to be agreeable to her. The conversation went on, and I saw that she did not recognize me, though now she was fully in the state of active somnambulism. She began to unbosom herself to me, and soon she confided to me her inmost thoughts.

"But who are you?" she suddenly asked, "and what right have you to question me?"

"Oh, you know me well. I am your old friend and devoted confidant for whom you have no secrets. How, have you forgotten Mr. Camille, your good Mr. Camille?"

"That's a funny name," said she, "but no matter."

Thenceforth *I had only to station myself on her left* in order to possess her confidence. There I was called Mr. Camille, while on her right I was still her "doctor." The thing was understood and there was no longer any need for me to change my voice or my position in any respect. I was transformed; but at the same time she also underwent a transformation, and she was no longer the mistrustful, circumspect person she was before. (She was saved from suicide thrice by this ruse.)

Suppose now that I had wished to give a deceptive demonstration of the force of a complex mental suggestion—changing my personality in the mind of the subject, without a gesture, without a word; changing my name; changing her attitude, her feeling toward me; "mentally" ordering her to confide in me.

To perform that marvel, all I should need to do would be to stand on the left of her.

Well, these things happen involuntarily through ignorance of the mysteries of association. We believe ourselves to be candid observers, the while we are unconsciously suggesting the phenomenon that is to be verified. Thus it is that the somnambulic subjects of the "fluidist" magnetizer see the fluid emanating from his finger-tips, while the somnambules of the hypnotizer see nothing, and those of the spiritist discover spirits everywhere, the same being invisible for the somnambules of the materialist. So it is, once more, that "pressure on the top of the head" produces, at Paris, the "somnambulic;" at Breslau, the "lethargic" state; at Manchester, "religious ecstasy," and so on. It is all "the story of Mr. Camille!"

Robert-Houdin long ago contrived a means of imitating "second sight." He trained his assistant—who played the part of the medium—so readily to understand his questions, that the latter always "saw" from a distance objects held in the hand, even when the hand was closed. If the question was "What do you see?" it was a coin. The question "What do you see *now*?" indicated a gold coin, and so on. Robert-Houdin could even convey to his subject, "mentally," the number of a bank-note simply by means of questions, the secret import of which was understood between them.

One often imitates this trick unconsciously when one, in thinking of a given phenomenon, has the habit of questioning the subject always after the same fashion.

Sometimes habit even is unnecessary, and one succeeds *ex tempore*, even in the waking state. I have often made the following experiment:

I lay a walking-stick on the ground, and say to a person that is hypnotizable, though not hypnotized: "Pass this limit if you please." The subject does so. "Once again!" He steps over the cane hesitatingly, and looks at me with mistrust. "And again!" He stands stock-still quite unable to step over the cane; his legs refuse to carry him.

Did I say that this was going to happen? No! Did I make any gesture whatever? No! I simply *willed* and *believed*. Then it is a case of mental suggestion? By no means—only *a suggestion guessed*.

Cumberland, the famous "mind-reader," came to Paris in 1884. It will be readily understood that, after having made the experiments already described, I could not be under any illusions with regard to the apparent thought-transference exhibited by him. Mental suggestion has nothing to do with his performances, but it is interesting and highly instructive to read the first reports of the newspapers. There we may see the difference between the experiments as performed, and as described, even when the performances are described by scientific chroniclers. There, too, we learn how small is the value of testimony when there is a question of a new and unknown phenomenon.

Having clearly perceived that the true medium in these performances was he who "thought," not he who guessed, I repeated Cumberland's experiments, and I published a series of articles on the subject in the *Gazeta Polska* ("Polish Gazette"), in May, 1884. Since that time the matter has been sufficiently elucidated in France, by the researches of Messrs. Gley and Ch. Richet, and I have only to formulate my own observations in order to complete theirs, without recounting the experiments in detail.

It is certain, then, that every thought having any relation whatever to space tends to produce unconscious movements indicating such relations. That is a habit, a nerve mechanism, in part hereditary, in

part acquired. In the case of an object hidden (to be found by the "mind-reader"), or of a person chosen (whom the mind-reader is to point out), one is thinking of the place where the object or the person is, and one simply *leads* the mind-reader who holds one's hand. One needs only to practice for one evening to perform the feats of the famous mind-reader; for notwithstanding all the extravagant stories that have been published about the matter, it does not even involve any special fineness of touch, no nice perception of pulse-changes or of imperceptible vibrations. *One must be able to go whither one is led;* that is all. The comic side of the thing is that one has not the slightest suspicion of what one is doing, and that people pay twenty francs to see a person point out an object they themselves have hidden. The melancholy side, on the other hand, is that our contempt for the "occult sciences" has rendered us ignorant of highly remarkable and highly instructive physiological phenomena, to that degree that we stupidly cry "Fraud!" when some simple, common fact is shown to us that ought long ago to have been studied and ascertained.

It has been necessary for a bold professional to traverse all Europe, playing tricks upon diplomats and princes of blood royal, in order to make science take account of the relations between "the physical and the moral." And it was the same with hypnotism, which would to this day not have been recognized by science had it not been for the public exhibitions given by Donato and Hansen.

In these experiments the one who leads you knows not what he is doing, the while thinking himself quite master of himself. I have known a very intelligent and highly educated lady with whom I could find a needle in a haystack. She would lead me with such certainty and with such force that resistance was out of the question. Once a little note was hid under a flowerpot. She indicated to me the flowerpot, and I began to feel about within it; then, with her hand, which I held loosely in my own, she made a negative gesture perfectly intelligible, and then another which said: Underneath!

Now, that lady not only was entirely unconscious of this expressive conversation, but she never would believe that it was by her unconscious motions that I was guided in the search.

"No," she would say, "that is impossible. You read my thought; I was very careful this time not to make any motion whatever." She was a person easily hypnotizable (hypnoscopic experiment: heaviness, paralysis, numbness).

There are some 60 persons in 100 with whom Cumberlandism succeeds more or less readily; thus, they are more numerous than hypnotizable subjects, who are not more than 30 in 100.

Usually the experiments are more successful with hypnotizable

persons. Nevertheless, there is a certain number of the latter—even of the best subjects—with whom you never will succeed. Why? Because the conditions of success in Cumberlandism are twofold:

1. An organic tendency to a duplication between the voluntary and the involuntary movements, which characterizes the majority of hypnotizable subjects.

2. A facility in concentrating one's thoughts and keeping up the concentration, which quite naturally and of necessity produces in every one this duplication.

Now, among non-hypnotizable persons there are some who possess this latter faculty in a high degree, while, on the other hand, it is sometimes lacking in persons easily hypnotizable, but who cannot concentrate their attention. When they pass fornent a person, they think of that person; but when they perceive a mirror they think of the mirror, and plainly the muscular indications become confused. Yes; there are persons easily hypnotizable who are incapable of concentrating their attention—a thing, be it said in passing, which contradicts Braid's theory.

In general, Cumberlandism rests upon the same physiological basis as "willing," though the external conditions are altogether different. In "willing" it is by the will that we seek to make the person we touch perform a given movement, and then we involuntarily impel him to its performance. In Cumberlandism, on the contrary, we have no such will, we simply think of a place—but we lead the subject all the same. At bottom the same principle is found in both; an *ideoplasty of movements* (realization[1] of the movements we think about) and, from the point of view of the one who guesses, a *mechanical suggestion.*

It is still a long way to mental suggestion. Yet these are the experiments that have contributed most to awaken in the minds of some physiologists the thought of studying true mental suggestion.

CHAPTER II.

PROBABLE MENTAL SUGGESTION.

SUCH were my judgments, such my doubts, when, in the month of March, 1884, I received from a well-known physician of Nice a letter, in which occurred the following passage:

"To-day I met a young man of 24 years, intelligent and educated, who wishes to be of service to science, and in whom can be produced, *in the waking state*, suggestion phenomena by word and *by thought.*

[1] Or actualization.—*Translator.*

He is a noctambule from childhood; so have been or are his mother, his maternal grandfather, and his maternal uncle. I have been able to make a few experiments with him. I imagined seeing a bird flying hither and thither in a room: I touched him and he saw the bird flying about in every direction. [Here follows an experiment in color-changes by *verbal* suggestion, which does not concern us.] He appears to be a little more sensitive on the left side of the body [than on the right]. I must see this subject again, for he is a very remarkable one.

[Signed] A. BARÉTY."

As the details of the experiment were not stated with precision, I was justified in supposing that the *questions* of the experimenter, and his *attitude*, might have suggested to the subject the hallucination desired. In fact, to suggest to the subject the idea of a bird flying, one need but look round the ceiling and ask if he does not see something in the air. And had details of what he saw been asked for, it is probable that the bird seen by the subject would be found very different from that imagined by the experimenter. Some weeks later I received a second letter, containing more details:

"Since my last letter was written, I have seen again the subject of whom I have spoken to you. He is in the hands of a magnetizer, with whom he came to see me. I have on my desk two statuettes, one bronze, the other ivory; these I placed side by side, three or four inches apart, and upright. Then I said to the subject: 'Look at these two statuettes; what is their color?' He answered: 'One is white (that on the right) and the other is dark.' Then placing my left hand in his right, I asked if he saw anything peculiar in looking at the two statuettes. As for me, I had *imagined* or strongly conceived the thought of the white one *quitting its place and becoming one with the brown.* He answered, after a few minutes, that the white statuette *left its place;* that it transferred itself *to the other side* of the brown. That was a little more than I had thought.

"Next I imagined (always without making the slightest sign) the statuettes *growing smaller*, and (my right hand being placed in the right hand of the subject) I asked him what he saw. He answered that he saw the statuettes growing smaller and smaller, till they were no bigger than a pin-head. In reality, they are each about five inches in height.

"Then I thought of them growing larger, and, *without my questioning him*, he told me that now he saw them growing larger and larger. He even lifted his head to follow this increase in their size, and seemed quite surprised at it. Imaging to myself, then, the statuettes growing smaller till they resumed their proper dimensions, I was told by the subject that he saw them growing smaller."

Here I interrupt the quotation to make some remarks. This experiment is certainly a good deal more important than the previous one. But it is far from being conclusive. First, the thoughts of the subject were fixed in advance, and limited to "something" about to happen to the statuettes. What could happen to them? A change of color?

Experiments on color changes had already been made in the preceding seance. The statuettes might change their places. The subject had this thought, but was a little "out" as to details. They might grow bigger. This the subject guessed. What association comes nearest to increased size? Diminution. This, too, the subject guessed. After the reality is falsified in two opposite respects; one, as a matter of course, feels the need of restoring the true state of things as they appear to our senses, and it is probable that the experimenter and the subject had this thought simultaneously. We need to know not only the details of the experiment—which has been described carefully—but also the conversation that went before, and all the conditions of the moment, in order to be sure that a train of associations and the *psychic atmosphere* were not the sole cause of the successful issue.

Such, in substance, were the observations that I made to the experimenter, and he was pleased to recognize the pertinency of a certain number of my objections. We may now return to the letter:

"After this experiment (writes Dr. Baréty), I made another and very interesting one on making him *find a hidden object.*

"Having made him *turn his head away entirely*, I took the ivory statuette and concealed it in my right hand, which I placed upon my hip. My left hand was not at this time in contact with his hand as it was before.

"I asked him to face about and look at the statuettes, which he immediately did. But, as he showed no surprise, I asked if he saw them both. He answered yes. Then, I said, 'Well, then, take the white one in your hand' He put his hand forth to where the ivory statuette had stood before, and seemed to bring it toward him and to examine it. But presently he moved his fingers as though conscious that he was grasping only a shadow, or that the object was vanishing. 'Where is it? What is become of it?' Forthwith he directed his eyes toward my closed right hand, placed on my hip (a position in which I had held that hand before seizing the object), and said to me, 'What have you in your right hand?'"

So far, I still see nothing but a transient hallucination, and an inference that easily enough may have been suggested by the immobility of the experimenter's closed right hand, which the subject, perhaps, for the first time noticed at the moment of his search. But let us return to the letter.

"I then asked him to turn and look in the opposite direction [an insufficient precaution, for it gives assurance to the subject that nothing is taken to any distance away], and then rapidly and noiselessly I hid the statuette in my waistcoat. Then I again placed my closed hand upon my hip as before. I bid him turn round and tell me quickly where the white statuette was, and to get it. He thereupon made his right hand perform a most singular movement. First he carried his hand to the spot where the statuette had originally stood, then, always slowly, he guided it toward the waistcoat, passing nigh to the hip

(where I had before held the statuette concealed in my hand), and following the track of the statuette.

"In conclusion, I repeated the experiment of increasing and diminishing the size of the statuettes *without my hand being in contact with the subject's, at the same time concealing my eyes.* It was a complete success. This last experiment seems to me very convincing. What think you of it?"

Yes; more convincing than the first, but unfortunately it was the *second*, repeated under the same conditions; consequently it is open to the doubts formulated above with regard to repeated experiments in general.

But while I raised these objections I was deeply interested in Dr. Baréty's experiments, and I sent to him a great many questions which I asked him to resolve experimentally. As for the experiments in finding a hidden object, when the subject followed exactly the track of the object itself, I frankly told the doctor that I did not understand them at all.

What was needed was a more systematic, a more rigorous, study of the matter. This Dr. Baréty knew as well as I, but unfortunately circumstances were adverse. Then, too, perhaps it was an excess of incredulity; but when there is question of an experiment in mental suggestion, I put no trust in anybody but myself. Besides, have I not told of a case in which I was myself deceived by an unnoticed circumstance or an unsuspected psychic mechanism? Nor is it out of presumption that I depreciate the testimony of others, who perhaps have taken precisely the same precautions I would myself have taken; but in matters like this it is impossible to recount all the little details that are essential for a full understanding of the situation, and conviction does not flow from the final result nor from the general conditions; what produces conviction is certain peculiar circumstances, the impression on the observer's mind, his personal sense of the impossibility of explaining the thing otherwise than by a direct psychic action.

I was therefore very glad to learn a month afterward that the subject and his magnetizer were about to come to Paris. I gave a good deal of time and study to planning experiments, and a seance was held in accordance with a programme drawn up jointly by Dr. Baréty and myself.

I commenced with the *hypnoscopic experiment.* It showed the subject to be a person of enormous sensibility: there was contracture and almost instantaneous insensibility of the whole arm. And this phenomenon could be produced or suppressed purely by verbal suggestion.

I wished at first to leave his habitual magnetizer, Mr. R., entirely at liberty, reserving to myself the right to make the experiments again

under different conditions. When one seeks to verify a phenomenon about which he knows nothing, one must not impose upon it at first a lot of conditions that may interfere with success, and yet, for all that, may not disprove the principle one is investigating, and the true nature of which one does not know.

"What results do you think you can produce with your subject?" I asked the magnetizer. He recited a whole litany of phenomena, out of which I selected the following three: 1.—Sympathic and attractive action on the right side, antipathic and repellant action on the left. 2.—Paralysis produced from a distance. 3.—Finding hidden objects.

"Do you think you can obtain with your subject any direct transmission by means of your thought alone?"

Much to my astonishment, the magnetizer replied in the negative. Yet that was the object of our meeting!

"I must use gestures," he said, "except in the third experiment, which can be performed without my taking any part in it. But I cannot guarantee thought-action pure and simple: with regard to that I am not at all sure."

What matters it? We will make the attempt all the same, as Dr. Baréty thinks he has succeeded often.

I shall not need to recount the details of the first experiment. Evidently—and R. himself shared in this opinion—it was simply the result of hypnotic training. It is "the story of Mr. Camille" once more, and it does not even prove the independence of the two cerebral hemispheres.

Second Experiment.—The subject turns his back to the magnetizer, who is in another room at the distance of about 25 feet. Dr. Baréty stays with the subject, I watch the magnetizer. The subject is counting aloud. At a signal from me the magnetizer "projects the fluid" with all his might. The subject ceases to count—he is paralyzed.

This experiment succeeded three times consecutively. I thought I noticed, however, that the magnetizer's cuffs were too noisy.

I now remained in the room. I walked up and down to prevent the subject from hearing the magnetizer's gestures. The experiment was a flash in the pan, that is to say, there was a delay of several numbers.

As the magnetizer was acting in perfect good faith, I asked him to take off his cuffs. Check again. We began once more, and now, though the magnetizer, at my request, made his gestures as noiselessly as possible, *the experiment was successful.*

Conclusion: Direct action was not proved, but no more was it disproved. But if direct action is to be admitted, there was reason to believe that the auditive impressions *assisted* in producing the phenomenon.

Third experiment.—This time something really new was presented. The procedure was as follows:

In the first place, every precaution was taken to avoid illusions.

An object of any sort was chosen—a book, for instance—which was placed on a table. (In this experiment the selection of the object is not important.)

The subject and his magnetizer being absent, I take this book in a direction chosen by myself, and hide it in a nook in the room not easily guessed. (I make an accurate sketch of the route taken by me in removing the book.) Baréty and I know where the book lies, but we take such positions in the room as to prevent our influencing the subject by any involuntary sign.

The subject is brought in blindfolded. The place on the table where the object formerly lay is indicated to him, but without naming to him the object. The subject is not asleep, but it becomes plain, as the experiment proceeds, that the concentration of his attention produces in him a state of super-excitation that is almost hypnotic. He begins by feeling of the spot indicated. He knows not what the object is, does not guess what it is, yet, strange to say, his fingers as they grope describe the contour of a book. One might say that the ghost of the book offers a resistance to his fingers. Having made sure of the form of the object and of the place it occupied before, he essays two or three directions, always *groping in the air*, and takes the true one. This he follows slowly, misses it twice or thrice, retraces his steps, goes on with greater confidence, and in three minutes finds the book. We say nothing, but he assures us that this is the object we had hidden.

I made a sketch of the path he took. On comparing the two lines, the second is found to be a little more curved.

In another experiment I purposely made two unexpected declinations; the track of the subject was straighter than mine.

Here, again, is something extraordinary: I selected as the object to be hidden a powerful magnet (the hypnoscope), without letting the subject know. He comes in, feels of the place where the magnet had lain, and stands motionless. "I cannot go on," he said; "my fingers are become stiff." In truth, there was a contracture not only of the fingers, but of the whole forearm. I was much surprised, but by means of gentle massage, without uttering a word, I freed him from the contracture and induced him to proceed. On reaching the mantelshelf, on which was the magnet, hid in a vase, the same phenomenon was seen. "It is there," he said, "but again my arms are stiff." He showed great fatigue at the conclusion of each experiment.

I shall now be asked, What is the solution of the enigma? All that I can say is:

1. All the experiments were successful, or nearly so.

2. There was no mental suggestion, or if there was, it played a secondary part.

3. The principal rôle was played by the subject's *tactile sensations*, which were exceedingly acute.

4. The object chosen might be "magnetized" or not, and taken to the hiding-place by an unknown person, and consequently neither the individual "fluid" nor certain olfactive emanations come here into play, or at least they are not necessary.

5. Unless we admit mental suggestion or the reality of a "dynamic ghost" (*spectre dynamique*) left at the place where before the hypnoscope lay, it must be confessed that in this case no scientific explanation whatever is possible.

6. Between the transfer of the object and the performance of the experiment it was essential that only a few minutes should intervene; else the "trace" of the object through the air vanished.

I may mention a few additional points of interest:

When questioned with regard to his own sensations or opinions, the subject told me that he considered the phenomenon as the effect of a *special tactile sensibility acquired by practice.* "When you are in a bath," said he, "you feel distinctly the difference in density of the two media, water and air. The water offers a greater resistance to your movements than does the air. Now, I have very much the same sensation in the air that an object has traversed; it is for me *more rarefied, it offers me less resistance*, and it is this less resistance mainly that guides me. I cannot tell you anything more about it. I do not feel quite master of myself in making this experiment, and the certainty of success depends precisely upon the degree of this peculiar state. I then feel *isolated* from all around me, I hear nothing, I exist only in my fingers, which, however, work without me. The more I reason the less do I succeed."

As for the experiment with the hypnoscope, evidently we must suppose that the presence of the instrument *magnetizes* the air for a certain time, or at least produces an electric change that we are unable to define. This supposition accords with Reichenbach's researches, which perhaps are worth repeating in spite of the non-success of the experiments mentioned in the beginning of the present study.

We decided to make a further test of the direct action of thought upon the subject. Touching him with my hand, I imagined to myself some object—its shape, color, feel. In this case the subject either saw nothing at all, or something very indefinite.

Setting before us a leaf of white paper, I imagined to myself a round yellow spot. The subject saw something gray. Again I imagined a black cross; he saw a round spot.

It appears that Dr. Baréty was more fortunate than I, and that with him the subject twice or thrice guessed the color that the doctor

had in mind, or at least the complementary color. But there was nothing decisive in these experiments—such, at all events, was my personal impression.

The following year (1885) Charles Richet published his remarkable essay in Ribot's *Revue Philosophique.*

He was inspired by an idea that I find to be at once simple and ingenious, and which may, I think, be stated as follows:

There are in physiological phenomena, no absolute limits—only a gradation. Consequently, if mental suggestion exists in an exceptional degree in some privileged subjects—and that remains to be proved—it must needs exist in a degree more or less inappreciable in everybody. That which in an isolated fact is inappreciable may be rendered appreciable by bringing isolated facts together. Statistic may light up an effect previously not noticed, and the calculus of probability readily shows how much belongs to chance and how much to a real agent. Thus one can find a rational, a premonitory (excuse the term!)[1] basis, before he attains direct proof of an extraordinary fact.

Mr. Richet set about making experiments (easily repeated with everybody) and grouping them, and reached the interesting conclusion that in cases where mental suggestion possibly was added to chance, there was always a slight surplus of successes. Here is a summary of the results obtained:

		Successes.	
		Probable.	Actual.
1.	In 1833 experiments with playing-cards	458	510
2.	" 218 " photographs, etc.	42	67
3.	" 98 " a rod	18	44
4.	" 124 spiritist experiments, so-called	3	17
	2,273	521	638

That is to say, in all these experiments there was a surplus in favor of suggestion.

I have repeated the experiments with playing-cards with four non-hypnotizable persons, and found the results very much the same. In order to be able to compare them, we must observe that for Richet's 1833 experiments the calculated probability was 0.250, and the actual proportion 0.278—a surplus of 0.028 in favor of mental suggestion. Now here are my figures:

		Successes.		
		Probable.	Actual.	Proportion of Actual.
C. R.	92 experiments	23	22	0.239
M. K.	30 "	7	7	0.250
B. A.	50 "	12	15	0.300
M. A.	107 "	26	32	0.299
J. O.	49 "	12	16	0.329
	328	80	92	0.283

[1] *Prémonitoire.* The meaning is obvious. The author it is that begs the reader's indulgence for using the word.—*Translator.*

That is to say, the proportion of successes was 0.283, supposing mental suggestion, while it was but 0.250 according to the calculus of probability, and 0.240 according to comparative experiment without suggestion—a difference of 0.033 in favor of the hypothesis.

These figures, it is seen, are even higher than those obtained by Richet; but the number of my experiments being much smaller, it is probable that were it increased the differences would be equalized.

In another series of experiments with another person (also non-hypnotizable, but very nervous and easily impressionable), upon guessing only the *color* of the cards, I obtained a difference still more marked in favor of suggestion, thus:

Without mental suggestion	0.42
By calculus of probability	0.50
With mental suggestion	0.60

A surplus of $\frac{1}{10}$. Mr. Richet thinks that experiments on the *color* of a card are inconclusive, because of a large influence of chance, which, with the probability of $\frac{1}{2}$, must efface the very slight influence of suggestion. That would be true *if the suggestive influence were absolutely the same in both cases*. But I do not think it is so.

The difference between *red* and *black* being clearer and simpler than the difference between *spade* and *club*, or between *heart* and *diamond*, the imagination of the subject ought to receive more readily a suggestion of the former than of the latter. Does not Mr. Richet himself say that, with a smaller chance, $\frac{1}{52}$ for example, for a full designation of the card "the conditions of suggestion are *bad*, as if the selecting from among 52 cards were too large a matter for suggestion to act clearly?" The remark is very just; but then *à fortiori* suggestion ought to act still more clearly when there is a question merely of a color.

From all his experiments, Mr. Richet infers the *probability* of the following propositions:

1. *The thought of an individual is transmitted* without the help of external gestures to the mind of an individual placed near him.

2. *This transmission takes place in different degrees* in different individuals; it is also extremely variable in the same person.

3. *This transmission is usually unconscious*, in that it acts rather on the unconscious intelligence than on the conscious intelligence of the individual perceiving and of the individual transmitting.

4. In healthy adults who are *not hypnotizable, the degree of probability of this transmission hardly* exceeds $\frac{1}{16}$ (we have seen that under exceptional circumstances it may amount to $\frac{1}{10}$).

5. *The general probability in favor of suggestion may be represented by* $\frac{1}{18}$.

The personal impression that results from all these experiments is as follows: the method is not of a kind to produce conviction; but if mental suggestion is a fact, this method has rendered a valuable

service to the cause by establishing for it a basis of probability, a real ground to stand on, and by awakening the curiosity of investigators.

Were it not for Mr. Richet's work, I should probably never have reverted to this unfruitful study and its manifold illusions. What induced me to persevere was the following passage:

"All my experiments (says Mr. Richet) were made upon non-sensitive persons, as my friends and myself; it will be interesting to know what effect they have on persons really sensitive, hypnotized, hypnotizable, hysterical, nervous, or trained by long practice in the perception of suggestions. Unfortunately I have had no opportunity to make *such* research, as I have not had at command a sensitive subject."

As one has only to provide himself with a hypnoscope and to enter a company of a score of persons, in order to find a good subject, I undertook a series of experiments for the purpose of verifying those made by the Society for Psychical Research, of London. Here are the results of my first seance:

The subject, Mrs. D., is 60 years of age, hypnotizable. (Hypnoscopic experiment: heaviness, paralysis, analgesia.) Chronic articular rheumatism, very strong constitution, very robust, remarkable intelligence, accustomed to literary work, a good deal of erudition, internal impressionability, without external signs; psychically active temperament, but quiet; of exceedingly gentle disposition. Her back is turned toward us. Mrs. P. and myself think of an object while we touch the subject; the latter is informed that the object is

OBJECT THOUGHT OF	OBJECT GUESSED
A Playing Card:	
1. Six of spades. (Prob. = $\frac{1}{52}$).	Six of black.
2. Ten of spades.	Red, not black, a ten-spot.
3. Knave of hearts.	Red, a king? A queen?
A Color:	
4. White.	White.
5. Yellow.	Yellow.
6. Black.	Black.
Any Object:	
7. A lamp.	A book, a cigar, paper. Result=0.
8. A silk hat.	Something blue, light. " "
9. An armchair.	A sugar-bowl, bureau, a piece of furniture. Result=0.
10. Salt.	A taste of salt.

21. Adam.	Jean, Gustave, Charles. Result=0.

A Number :

22. Ten.	Six, twelve, nine, ten.

Any Object :

23. A book bound in blue satin.	Violet color, pink. Result=0.
24. Gold pencil case on a blue ground.	Something black on blue. Result=0
25. Ace of spades on a black ground.	Something black, blue, a card, ace of clubs.

A Musical Instrument .

26. A trumpet.	The violin. Result=0.

A Digit :

27. Three.	2, 5. Result=0.

An Object in the Dining-room :

28. A plate with figure on it.	A plate with figure.

A Taste :

29. Of salt.	Sour, bitter. Result=0.
30. Of sugar.	Sweet.
31. Of strawberries.	Of an apple, grapes, strawberries.

The subject was visibly fatigued, and we interrupted the experiments.

I was much surprised. Of 31 experiments at least 13 were entirely successful, though often the probability was exceedingly small ; even the misses in some cases presented evident analogies. And hardly 12 out of the whole 31 could be regarded as absolute failures. The first three, for example, though not entirely exact, plainly uphold the probability of suggestion.

One doubt alone troubled me. I have already explained what I call the *psychic atmosphere*. All the objects thought of, except a few cards drawn at random, were chosen during the seance by myself or

by Mrs. P. Now, it well might be that we were all three quite unconsciously borne along, so to speak, by a current of associations. This supposition may seem improbable, but in making it I had in mind a prior experiment of my own that was truly astonishing.

There were five or six of us staying with friends in the country. We amused ourselves as we could; among other things by playing tricks with cards. Then we passed to guessing. Having by chance twice or thrice guessed a number chosen between 0 and 6, and several cards chosen mentally, I thought I noticed that after repeated experiments there was set up in our minds a mechanical series of cards or of numbers, based on contiguity, likeness, or contrast, and that this gave me a *presentiment* of the card or number to be selected immediately. I had only to give the rein to this unconscious and unreasoned conjecture in order to perceive in my imagination the image of a card that was *in the air*, so to speak. I was almost certain that now it was the turn of, say, the king of diamonds, and I would ask my neighbor to think of a card. He would think of the king of diamonds.

It was no suggestion from my neighbor, for before he chose his card I had made up my mind to say "king of diamonds." And often in such cases it happened that another person would remark: "Well, that is curious! I thought of the same card!" Thus, it was *in the air.*

Sometimes I have been able to discover the probable mechanism of this enchainment. Thus, 28 was chosen next after 47 probably because $4 \times 7 = 28$. Again, if among the numbers between 1 and 9 one chose 8, that is, a number near to 9, another person would choose 2 or 3, to be farthest away from the former; 2 and 3 would lead to the thought of 6; then, in order not to take again the numbers already used, the choice would fall upon 4 or 5, associated to 3 and 6, which were pronounced more aloud than the others, and so on. It is impossible to foresee all these relations between numbers: if they chanced to agree in several persons at once they constituted the *psychic atmosphere*, playing the part of a prompter.

Evidently the mechanism of these guesses seldom suffices to explain certain unexpected coincidences; but being a determinist in psychology as in other matters, I have said to myself: I am ignorant of this mechanism; therefore I cannot justify the general hypothesis by proofs; yet, all things being determined by an enchainment of causes and effects,[1] it is conceivable that an omniscient intelligence, knowing all the impresses of sensations in our brains, all the connections of our thoughts, all our habitudes, weaknesses, and other qualities,

[1] This clause furnishes a definition of the term "determinist:" One who holds that all things are determined by an enchainment of causes and effects. "Determinism" contradicts "free will."—*Translator.*

might easily calculate or foresee not only our choice, but also the answers of the subject. And as it is certain that the unconscious of somnambules is a Grand Master in occultism, who is there that may boast himself to know the limits of its power? The fact that my subject was not in somnambulism was no obstacle, for I have long been convinced that *all* the phenomena of somnambulism may present themselves isolatedly and momentarily in the waking state.

I beg the reader not to be surprised at these rather conjectural speculations. In dealing with a phenomenon so controverted, so extraordinary, when after long years of research one sees that all his convictions, acquired theoretically and experimentally, are shaken, one defends himself as best he can.

But to return to the facts. Here are three experiments in favor of the psychic-atmosphere hypothesis, hastily made upon another person, not hypnotizable:

A Color:

OBJECT THOUGHT OF		OBJECT GUESSED
32. Red.	|	Pink.

A Flower:

33. Lilac.	|	Lilac.

A Person Present:

34. Mr. J.	|	Mrs. D.

The general outcome of these three experiments seems quite favorable to the theory of transmission. But let us consider the circumstances. The subject is told that there is question of some color, and he guesses it only approximatively; the color was *red;* it becomes *pink.*

The subject is told that the test is some flower. A bunch of lilacs was on the table; every one noticed it, and it was uppermost in the minds of all. Then, the question being about a matter a little more remote, with the probability still strong, only some dozen persons being present, there was a check. Not only does the subject not guess the person, but he names a woman instead of a man. Consequently, these three experiments are almost valueless—and, when I say *almost,* that is solely because of a certain resemblance between red and pink; but the thought of pink may have been called up by a purely fortuitous cause, that is to say, one having nothing to do with suggestion.

Let us now come back to our first subject. Here is a second series of experiments, made with greater precaution, care being taken to avoid the enchainment of associations (May 2, 1885).

Any Object:

OBJECT THOUGHT OF		OBJECT GUESSED
35. A bust of Mr. N.	|	Portrait . . . of a man . . a bust.

Any Object:

OBJECT THOUGHT OF	OBJECT GUESSED
36. A fan.	Something round. Result = 0.
37. A key.	Something made of lead . . . bronze . . . it is of iron.
38. A hand wearing a ring.	Something shining, a diamond . . . . a finger-ring.

A Taste:

39. Acid.	Sweet. Result = 0.

A Shape:

40. A Square.	Something irregular. Result = 0.
41. A circle.	A triangle . . . a circle.

A Letter:

42. M.	M.
43. D.	D.
44. J.	J.
45. B.	A, X, R, B.
46. O.	W, A; no, it is O.
47. Jan.	J . . . (continue!) Jan.

Third series, May 6, 1885. Twenty-five experiments were made, notes of which, unfortunately, I have not kept, except as to the following, which surprised me most. (The subject has her back turned toward us, holds a pencil, and writes the thought that comes to her. We touch her back lightly while looking on letters written by ourselves).

OBJECT THOUGHT OF	OBJECT GUESSED
48. Brabant.	Bra. . . (I strive mentally to aid the subject, saying nothing.) Brabant.
49. Paris.	P. . . aris.
50. Téléphone.	T. . . éléphone.

Fourth Series, May 8. Same Conditions.

51. Z.	L, P, K, J. Result = 0.
52. B.	B.
53. T.	S, T, F.
54. N.	M, N.
55. P.	R, Z, A. Result = 0.
56 Y.	V, Y.
57. E.	E.
58. Gustave.	F, J, Gabriel. Result = 0.
59 Duch.	E, O. Result = 0.
60. Ba.	B, A.
61. No.	F, K, O. Result = 0.

A Number:

62. 44.	6, 8, 12. Result = 0.
63. 2.	7, 5, 9. " = 0.

(I endeavor to have represented in the subject's mind the written numbers, not their sound.)

64. 3.	8, 3.
65. 7.	7.
66. 8.	8; no, o, 6 9.

Thirteen experiments followed with fantastically drawn figures, only five of which presented a general likeness, without much exactitude.

A Person Represented Mentally:

67. The subject.	Mr. O. No, it is myself.
68. Mr. D.	Mr. D.

Any Image (or View) Whatever:

69. We imagine a crescent moon, Mrs. P. representing it to herself with a background of clouds; I, with one of deep blue.	I see the clouds flitting . . . A light . . . (with a look of satisfaction) it is the moon.

If after these experiments any one had asked whether I believed in thought-transference, I should have answered affirmatively. From the point of view of conscious, scientific reasoning, one must have surrendered to the evidence. Chance could not have produced so many fortuitous hits. For example, if we look only at the experiments with letters, *leaving out of account the whole words guessed*, of 20 experiments 15 succeeded, whereas probability allows only *one* success in 24, or o in 20—zero against fifteen! To hit the chance guess of the three-letter combination *jan*, would have required 25^3 (= 15,625) *experiments* without suggestion, while with suggestion *one* sufficed.

Thus, from the objective standpoint, my skepticism might well surrender before the eloquence of the facts. But—and here is the oddity of the thing—in problems of this kind the observer's *subjective impression* is sometimes worth more than a purely empiric showing. Evidently the observer must have a general scientific routine and a special acquaintance with the phenomena belonging to it; but then it is upon his instinctive *subjective impression* that I should most rely. He may give me all the details—and it is impossible for him to give *all* the details of conditions and circumstances—but if I do not see that inwardly, subjectively, he is not merely astonished, but convinced, conquered by the facts observed, without having his reason upset, as may unfortunately happen—it was so with Zöllner[1]—I would give no particular credence to his revelations. I should prefer an almost entirely defective experiment, but accompanied by that personal

[1] Slade, the American spiritist, succeeded in making the German mathematician Zöllner believe in a fourth dimension of space, by showing to him a knot produced on a single cord after the two ends of it had been tied together and sealed with wax bearing the impression of Zöllner's seal!—*Translator.*

impression of an instructed and honest man which is expressed in the cautious yet decisive phrase: "There's something in that."

Now, this personal impression was mine when I made those hurried experiments; but the thing that was always lacking was that other impression, subjective also, but more decisive: "Here is direct transference of thought."

Singularly enough, nearly every time that the subject was going to guess our thoughts, I had a presentiment that it would be so. It seemed to me that, despite all precautions, and though we were all in perfectly good faith, there was a certain trickery on the part of our unconsciouses, and that they were fooling us. It seemed to me that even in choosing the objects hardest to guess, I was astutely making the choice that most facilitated success; that even when a card was drawn at random, I substituted another for it under some insufficient pretext, even forgetting this manœuvre, and remaining quite at rest in my conscience, while my partner (*aide*) nothing suspected.

I fear I shall be misunderstood. I am speaking of a phenomenon almost inappreciable, of operations infinitesimal, transient, more or less unconscious, caused by the psychic atmosphere. I have been long used to make psychological observations; they have been the principal occupation of my life, from early childhood I might say, for since my fifteenth year I have been taking daily notes (some of them published in my native language), and I was but seventeen when I wrote my first dissertation on "Methods of Psychological Study," published in 1869, wherein I showed (for the first time, I believe) how the phenomena of hypnotism may be exploited under the form of a special method by *positive* theoretic psychology.

Consequently I do not wish to be suspected of any sort of mysticism, and I think I have the right to claim for myself the routine that is necessary for making exact observations. But just because of this long practice I have reached some empiric subtilties very difficult to express. Psychology has throughout for me an aspect widely different from what one sees in the best works on our science. The psychology of the day seems to me gross and crude in view of the subtilties of real life as I see it. The theory of association of ideas, for example, which has been made, and with reason, for the nonce, the sole ground of the whole psychology of phenomena, is for me only a partial and quite inadequate expression of the mechanism of psychic life. It is but a rough draft of a delicate mechanism. It may suffice for the needs of instruction in the elements of psychology, but not for a finished science. I am free to confess that with the association theory of to-day I do not even see why our ideas associate, and in general why they live, circulate and produce sensible effects. And yet I am a determinist, and it is no faculty, no obscure force, that I would add to the association theory to make it true to fact and life.

The question is one of details, but of details that stand related to the current theory of association as vision through a microscope is related to direct vision.

For explaining the larger phenomena of psychic life this association-anatomy is well enough; the thing we need is a microscopic histology of association when we have to do with rare phenomena, *i. e.*, with phenomena *rarely noticeable and rarely noticed*—for that, too, is a point of my personal separatism in psychology, to wit, that rare phenomena are such *only because we are rarely capable of seeing them.* On the other hand, we should be less ready to discern an enchainment through contiguity, likeness, or contrast, in time or in space, were we to see things through a psychological microscope which should oftentimes distinguish like phenomena, assimilate contrasts and dislocate contiguities, interposing a number of intermediate links and agencies.

Unfortunately, when it comes to setting forth details precisely, two things are lacking: first, clear vision of these details, and then, even when they are seen passably well, the possibility of expressing them correctly. Here we may call to mind the vicious circle of the sophist Gorgias. Plainly our skepticism is not, like his, nihilistic. We do not see clearly to-day, we shall to-morrow, and no doubt we shall little by little find new words for new ideas. In the meantime it is better to stand still where we are than to create an incomprehensible language and to talk Volapük under pretense of propagating a universal science. We have had plenty of Volapükian psychologies which, albeit they were created by Kants and Hegels, no longer exist in the estimation of exact science. All this notwithstanding, the Kants and Hegels may have had profound ideas that will be understood, *better than by their authors*, a few centuries hence.

I have often mentioned the unconscious. I have even personified it a little, without any back-thought,[1] however. I concede to German psychology the great merit of having brought to light that absolutely true and fundamentally necessary theory. But see what happened when men set about defining it prematurely; see what it has come to be in the deft and reckless hands of Von Hartmann; a fantastic romance of the unconscious, an Edgar A. Poe story, not even as near the facts as a story of Jules Verne's!

Hence it is that I choose to content myself with a few hints that to me seem clear, instead of plunging into subtilties that I do not myself quite understand. Later, when we come to certain details of the question, we shall see what it may be possible to add.

So, then, I was convinced of the reality of the *facts* of mental suggestion, but not of suggestion itself. It remained to formulate the theory of the facts, and that theory appeared to me far removed from

[1] *Sit venia verbo.* It is meant to translate *arrière pensée*—the thought (or intent) that is behind, or *lies back of*, an overt act or speech.—*Translator.*

the theory of *direct action of mind upon mind*, such as Mr. Richet received.

Finally, here perhaps were two or even more different processes to be discovered.

First, a *concordance* between two unconscious mechanisms, as between Leibnitz's two watches, a concordance resting on a sort of harmony preëstablished through the mutual interchange of the ordinary conscious sensations, and in which the object chosen as well as the object guessed is determined independently the one of the other, but by one self-same unconscious determinant set of works.[1]

Then, in some cases, a true *perception* of thought by *intermediation of external signs* that may easily escape us, seeing that so perceptible a sign as the tension of the muscles in the direction of the object thought of has taken so long to be discovered. There would thus be an exaltation of perception, but of the normal perception for physiognomic, pathognomic, and ideognomic signs, that usually enable us only to distinguish joy from sadness, quiet enjoyment from intense pleasure; sympathy, distrust, irony, or sincerity, in the touch of a hand or in the tone of a voice; whereas here, in virtue of an exceptional perceptibility, those signs would enable us furthermore to divine whether one is thinking of *yellow* or of *blue*, of a *round* figure or a *square*.

Finally, over and above all normal perceptibility there is perhaps ground to suppose a transmission, *always indirect*,[2] of vibrations produced by the thought itself, and capable of reconstructing the thought, like as the human voice produces undulatory telephone currents that can reproduce speech at another like station.

Henceforth all this was possible, and it behooved to look forward to an unheard-of complexity of phenomena. Consequently it was my wish to simplify at least the conditions of experiment. In the experiments already recited this was impossible. The subject had always to be notified in advance that the experiment was to be made, consequently his unconscious was put on its guard. The subject could take for granted that we would avoid repeating the same experiments, and that if at the seance before we thought of *blue* and *yellow*, it would now be the turn of *red* and *green*.

We had to circumscribe, and that pretty narrowly, the category of objects to be chosen, and then the thought of the subject was also circumscribed in advance, and had to rummage in only one of the receptacles of memory, there to concentrate all the perspicacity of his divining power.

[1] *Rouage*—The works of a watch, the "movement."

[2] The meaning of *indirect* here is gathered from the author's illustration. The human voice is one thing; the undulatory current another. The result in a receiving telephone is the human voice *indirectly* transmitted: it has suffered transformation and retransformation in the passage. The case may be the same when thought is supposed to be transmitted from one brain to another.—*Translator*.

Of objects belonging to the same category, only a very small number will be in sight and capable of being chosen for the experiment. Suppose the thing to be thought of is a flower, assuredly one will not choose *Scrophularia nodosa*, nor *Contrayerva officinalis*, which one would find it difficult to bring clearly before his imagination: one will choose a rose, a lilac, a violet, and then from time to time he will meet with success. The subject will *divine* (that is the word) our thought. But that is not what I want. I want a fact of actual thought-transference wherein shall be nothing to be divined, and wherein the unconscious may calculate as it will without prejudicing the precision of the experiment.

What I want is that a subject in nowise forewarned, nor expecting anything, neither seeing nor hearing anything, shall manifest the action of my thought by some reflex action *visibly connected with that psychic impulse*. I shall be content with any sign however slight, but it must be a sure sign and a *constant*, and it must be one that cannot be referred to any other cause but my mental action. That is what I want; and till I have in my hands a fact of that sort I shall not have *subjective impression* of the reality of a mental action; but till then it will not be worth while to make a special, thorough study of the matter and to brave the prejudices of the scientific.

The fitting occasion for that decisive experiment was not long in coming.

CHAPTER III.

TRUE MENTAL SUGGESTION.

I WAS attending a lady suffering from hysterepilepsy, whose ailment, already of long standing, was aggravated by an attack of suicidal mania. Mrs. M., 27 years old, strong, and of good constitution, has the look of perfect health (hypnoscopic exp.: insensibility and almost instantaneous contracture of the entire arm). Convulsive seizures of the major hysteria dating from childhood, almost. Hereditary influences very strong. For some time past, besides these principal symptoms, at sundry periods, attacks of mental alienation, with congestion of the anterior lobes and anæmia of the posterior lobes of the brain; paralytic, nervous, fainting fits, and epileptic seizures of brief duration. Transient contractures and amblyopy, more marked on the left side. A single *hysterogenic* point beneath the left clavicle. A *delirogenic* point on the right occiput corresponding to the superior occipital fossa. No anæsthesis. Pressure on the ovaries arrests the attack for a moment. Sensitive to tin, but also to other metals in different and varying degrees. Temperament active and sprightly,

combined with extreme *inner* moral sensibility, that is to say, without external signs. Character eminently truthful, kindliness very marked, disposition to self-sacrifice. Intelligence remarkable, many talents, capacity of observation. Momentary lack of will-power, painful indecision, but afterward exceptional firmness. The least moral fatigue, an unexpected impression of small importance, whether pleasant or painful, is reflected on the vasomotors, though slowly and imperceptibly, and brings on an attack or a nervous fainting fit.

One day, or rather one night, her attack having passed away (including the delirium phase) the patient was sleeping quietly. Awaking suddenly and seeing us (a woman friend and me) beside her bed, she begged us to go and not to tire ourselves for her sake to no purpose. She was so pressing that in order to save her a nervous crisis we left her. I went downstairs slowly (she lived on the third floor), but halted several times and listened, being haunted by a presentiment of mischief (she had given herself several wounds a few days before). Reaching the courtyard I halted once again, considering whether I should leave or not. Suddenly the window was opened noisily, and I saw the patient lean out with a rapid movement. I sprang to the spot whereon she would fall, and mechanically, without attaching any importance to what I did, I concentrated my will to withstand her fall. It was a silly thought, and I was but imitating the action of billiard players, who, foreseeing a *carambolage*, strive to stop a ball by gestures and speech.

Yet the patient, already leaning out over the window sill, stopped and drew back slowly and by degrees.

The performance was repeated five times in succession, and at last the patient, as if fatigued, stood motionless, her back resting against the frame of the window,[1] which remained open.

She could not see me, for I was in shadow and night was falling. At that moment Miss X., the patient's friend, ran in and seized her by the arms. I heard them struggling and hastened upstairs to help. I found the patient in a fit of insanity. She did not recognize us, taking us for robbers. I succeeded in releasing her grip on the window frame only by pressure on the ovaries, which made her fall upon her knees. Again and again she tried to bite me and only with much difficulty was I able to put her again in bed. Keeping up with one hand the pressure on the ovaries, I brought about the contracture of the arms, and at last endormed her.

Once in the somnambulic state, her first words were, "I thank you and beg pardon." Then she told me that she had wished to throw herself out of the window, but that whenever she attempted it, she felt herself "lifted from beneath."

[1] The "French" style of window, hinged on the side.—*Translator.*

"How so?" I asked.

"I do not know."

"Did you suspect I was there?"

"No; it was just because I thought you had gone away that I wanted to carry out my plan. Yet it seemed to me now and again as if you were beside me or at my back, and that you did not want me to fall."

This experiment—or rather accident—was, of course, not enough to prove action at a distance. But it suggested to me the thought of studying the question anew. As there was an appearance of action, it was a very easy matter to test it experimentally. But in order to have the conditions just what they ought to be, I breathed not a word to any one about what I purposed to do, and I even resolved to wait a few days, so as to arrange the details of the experiment.

I had been in the habit of endorming the patient every other day, and I used to leave her in profound slumber (aideic state) while I made my notes. Two months' experience gave me the assurance that she would not stir till I should approach her in order to induce somnambulism proper. But this day, after taking a few notes and without changing my attitude (I was several yards distant from the patient, outside of her field of vision, with my note-book on my knee and my head supported by my left hand), I pretended to be writing, making the pen scratch as it had been doing, but inwardly I concentrated my thought upon an order I gave her as follows:[1]

December 2.

1. Lift the right hand!	1st minute: no action.
I watch the patient, looking through the fingers of my left hand on which my forehead rested.	2d minute: agitation in the right hand.
	3d minute: agitation increases, patient frowns and raises the right hand.

This experiment, I confess, moved me more than any other.

2. Get up and come hither!	Patient frowns, stirs, rises slowly and with difficulty, comes to me with hand outstretched.
(I lead her back to her place without uttering a word.)	
3. Take off bracelet from left arm and hand it to me!	No action.
I touch her on the right arm, and perhaps give it a slight push in the direction of her left arm, while I concentrate my thought upon the order given.	She puts forth her left hand, rises, and goes in the direction of Miss ——, then toward the piano. She sits down exhausted. She takes off her bracelet. (Seems to be reflecting.) Gives it to me.

[1] Most of these experiments were communicated to the Society of Physiological Psychology, January 25, 1886. Some of them have been published in the *Revue Philosophique*, August, 1886.

4. Get up, draw the armchair up to the table, sit beside us!	She frowns, gets up, and comes toward me.
	"I have yet something to do."
	Seeking something; touches the stool and displaces a glass of tea.
I check her hand thus astray.	She steps back, *seizes the armchair, pushes it toward the table* with a smile of satisfaction, and sits down, dropping into the chair through fatigue.
	"They tell me to carry, and do not tell me what. Why do they *speak* so indistinctly?"
5. Hold out the right hand!	She stirs.
	Holds the right hand out.
	Tries to rise.
Stay seated!	She settles herself again in the chair.
Give the left hand!	Movement of left hand, but she does not hold it out. Rises and goes to the sofa.
Give the left hand!	Gives the right.
Not that; the other![1]	Gives the left hand.

It is to be remarked that even in the waking state the patient often mistakes one side for the other.

During experiment 5 *active somnambulism* manifests itself; the patient converses with us in a playful vein. She no longer obeys the orders. "I am now going to sleep," she said.

She slept. During the sleep there were some traces of an hysteric attack. At length she seemed to awake. "There is a tingling in my head," said she, "that will not let me sleep. I don't want to sleep any longer. Sit by me." "Are you still in somnambulism?" I asked. "Yes." (This patient was able to note each phase of her state with wonderful precision—a very rare circumstance, indeed. I often pretended not to recognize the state she was in, so that she herself might describe it.)

"And if you go to sleep in that state, is it all the same as if you were in the waking state?" "Oh, no; for now the legs and the body go to sleep first, and then the head. The head, too, awakes first, so that I can easily tell whether I have slept well or not; whereas when I go to sleep from the waking state, I go to sleep in the head and I know nothing more. Then, too, when I converse, being magnetized, *I am resting all the same;* whereas if I were to converse in the waking state my head would be tired and drowsy."

[1] All these orders were given mentally and without gesture. No word was spoken.

December 3.

Mrs. M. is endormed by the process of gazing,[1] and falls into a very profound slumber (*paralytic aideia*).

6. Answer whether you hear me?	No action.

I put the same question *vivâ voce*. She does not hear. A moment later she stirs slightly.

"You did not hear me just now?" I asked. "No!" "Why?" "Because my sleep was too deep." "Will there be an attack this evening?" "No!"

I therefore left her to herself, and a few minutes afterward began the experiments again.

7. Give me your right hand!	Frowning.
Give me your hand!	No result.
No matter which hand.	Gives the left.

If at this moment I speak to her, touching her at the same time, she replies; if I speak to her without touching her, she hears only unintelligible sounds.

I tell her that I am obliged to be absent fifteen minutes; once outside, I try to call her mentally:

8. Come hither!	Frowning.
	General agitation of the body.

Here the experiment is interrupted by a singular accident. The action from a distance produces in her a general hyperæsthesia, and in that state she "feels incommoded by something on her right;" "an unbearable stench horrifies her;" "an imaginary noise, produced by the irritation and congestion of the brain, prevents her hearing" me.

"It seemed to me," she said, "that I must get up and walk about; but that horrible atmosphere was suffocating me. *That thing* (*celà*) prevented me; *that thing* does not love you, but *that thing* is ashamed to confess it."

"What is it, pray?" "I do not know; but deliver me from *that thing*"—and she made gestures of repulsion toward the right. We saw nothing out of the common in that direction. At last I noticed that there was on the flower stand a new plant, and I removed it. "Ah, at last!" said the patient; "thank you; I was near having a paroxysm."

The new plant had been brought that day by one of her friends, a lady for whom, in the normal state, she had a strong liking, but whom in the somnambulic state she could not endure even at the distance of several yards. This I knew already, having witnessed a terrible

[1] *Par le regard.*

paroxysm caused solely by the presence of this lady; but it never occurred to me to suppose that an *object* that had belonged to her would have the same influence. First I thought the patient's abhorrence of the plant might be due to its odor, but it was nearly odorless. Then I made several experiments with objects coming from the lady, mixed with other objects. For instance, I placed upon the couch beside the patient, yet at some distance, a roll of music brought by this same lady. Having just touched it lightly with her hand in making a gesture, she drew herself away from it quickly, asking who it was that was treating her so ill. So with other objects. She never made out what was the matter, but she always was conscious of an antipathic influence. Even a playing-card coming from the lady, and shuffled with several others, was rejected as "disagreeable." I must add that the young lady in question was a great friend of Mrs. M., and was jealous of the influence I exercised over my subject.

December 5.

(Our patient, on awaking, passes momentarily through a transient state of monoideism, and then she has always a sense of the mental state of the persons around her. She will say: "Why have you greater confidence to-day?" "Why is she so worried (or so happy) to-day?" And so on. But once fully awake, she no longer has this sense.)

9. An experiment in the state of *genial, active somnambulism.*[1]	No action. (Patient is half awake) "Where is she—Mary? She must have a wearisome task to perform. I believe she is thinking of nothing, *for I have no feeling of her.*"

Wishing to sit back of the table I came near falling, the chair being lower than I thought. The patient uttered a cry. "What is the matter?" I asked. "It seemed to me," she answered, "as though something were giving way *beneath me.*"

If any one pinches me she complains of it, yet she does not know it is I that suffer. I tell her that I want to put her a few questions. "Then endorm me a little more," she said; so I make a few passes in front of her eyes. At this moment she is in *passive somnambulism, i. e.*, she answers easily and volubly every question put by me (and by me alone), but does not of her own accord say anything.

"Can you tell me," I ask, "in what degree of sleep you undergo the action of my thoughts?"

"When the members sleep in very deep slumber," (each part of

[1] *Somnambulisme actif gai.* In the original this exp. is numbered 8, and the words of the subject are *given in the text*, not in two columns, like the others. The author forgot to state the order given to the subject.—*Translator.*

her body can be put to sleep and awakened separately), "and when I cannot think by myself."

"But if, then, I order you to rise, you will not be able to do so?"

"Alone, no; but if you will it strongly something will lift me."

"Do you know beforehand what I require of you?"

"No, but it gives me an impulsion; and I prefer you to divide your thought. I cannot take it in all at once. I do not understand the words, and I believe that you might think in any language whatever; I feel only an impulsion that comes upon me and at last controls me." (Here I gave some explanations to Marie.) I now asked: "Did you hear what I said?"

"I heard you speaking, but understood nothing, for you had not the intention to be understood by me."

"If I do not address my speech to you, what do you do mentally? Do you think of anything?"

"When I am in light sleep as now, I can think well *if you are near me;* but if you withdraw there is a veering in my head[1] as though you were to leave me in a dark room."

"And if I were to put you in a deeper sleep?"

"In that case I should know nothing, and were you to leave me, I should remain just so, not suffering anything."

"In what state, then, in your opinion, is thought-action easiest?"

"*For that the sleep must be very deep, but I must hear you all the same.* In fact, I hear you always, or at least I think I do (plainly the somnambule could not know whether she heard me in the state of absolute aideism); still, sometimes I hear only detached words; for example, you put me the question, 'Do you hear me at this moment?' and I hear only 'hear' and 'moment;' or again, I hear all the words, but each word isolated, so that when you are at the end of a phrase *I have forgotten the beginning;* the first words are gone from me (monoideism). Sometimes, too, I hear you and understand you well, but I have not the strength to answer."

"And in the state you are in at this moment could you receive my thought?" "No," she said. I gave her, mentally, the order "Awake!" No result. But some minutes later she said of her own accord: "Awaken me;" and then I was able to awaken her from a distance. (A simple yea never sufficed to awaken her.)

December 7.

The patient is in the *aideic* state and partly tetanized—arms in contracture, the legs a little stiff.

10. Rise, go to the piano, take a box of matches, bring it to me, light a match, go back to your place!	She rises with difficulty. Comes near me.

[1] *Il se fait un revirement dans ma tête.*

Go to the piano!	Goes to the piano, but passes beyond.
Come back!	Turns back.
Still farther!	Goes toward the door.
I stop her with my hand.	Returns to the piano.
	Seeks too high.
Lower!	No result.
Lower!	Lowers her hand.
Take the match-box!	Touches the box, then retreats.
Take the match-box!	Touches it again, and takes it.
Come to me!	Comes to me.
Light!	Wants to pass the match-box to me.
Light!	Takes out a match.
Light!	Lights it.
Go back to your place!	Returns to her place.
11. Bring the right hand to my lips.	Her right hand stirs.
Raise it!	No result.
Raise it!	Raises the hand.
Give it to be kissed!	Brings the right hand to her face; removes her cravat.
Not that! To my mouth!	Brings her right hand near my head.
To the lips!	Brings it to my lips.

December 9.

The patient is sleeping well; *aideic* state, with tendency to contractures.

12. Lie on the right side.	No result. She rises and stops; her whole body contractured, perhaps under the influence of my gaze, which was fixed intently upon her.
I suppressed the contracture by means of a light massage. I take her hand, and, at a given moment, try mentally to	
13. Produce contracture in the left arm.	The left arm almost instantly becomes stiff.
14. Lie down!	No action.

At this moment there is a state of hyperacusia: the slightest noise irritates her; then she falls again into a state of general immobility.

Then suddenly: "I do not hear your thoughts well, because either I sleep too soundly or not deeply enough."

Opening her left eye produces catalepsy in the right arm, then in both arms. Opening the right eye produces no result at all.

15. Ordered to scratch her cheeks.	No action.

At this moment a flaming match held before one of her eyes, opened for the purpose, produces no reflex action. Even the contraction of

the pupil is not as great as usual, though but a moment before the contraction was nearly normal, and the patient said she saw "a little brightness." Now she says she sees nothing. I awaken her; she seems to be pretty well, but little by little a paroxysm comes on. I stop it by magnetizing her anew.

December 11.

(Experiments made in presence of Mr. Sosnowski, engineer.)

The patient doing well. I put her to sleep in two minutes, and show the three principal states, viz.:

1. Aïdeia (without thought, very deep sleep).
2. Monoïdeia (one thought alone possible).
3. Polyideia (somnambulism properly so-called).

Then by means of a few passes in front of her eyes, I deepen the sleep to the transition degree betwixt aideia and monoideism. She now hears me even without touch, but she is totally paralyzed and insensible.

16. Come to me! I change position and hide as far away as possible.	She rises and comes straight to me.
17. Shake hands with Mr. S.! (The experiment was proposed by Mr. S.)	She extends the right hand and gives it to Mr. S.

At this moment the opening of her eyes did not produce catalepsy. The touch of Mr. S., as of every stranger, is highly disagreeable to her. She will not allow them even to come within two feet of her.

December 18.

18. An experiment in the state of active somnambulism, before the paroxysm.	No action. A few minutes later the paroxysm comes. Then I put her into deep sleep for the whole night.

She awoke quite well the next day.

December 27.

In endorming the patient *I prolong the passes beyond the usual time*, for without the passes she fell asleep with difficulty. The sleep becomes very deep. She no longer hears me at all. The pulse is weak and uneven, pulsations 80. The respiration is short and intermittent. I quiet her by laying my hand upon the pit of the stomach.

19. The subject is to go to the table, take a cake and give it to me. (Seeing that the sleep is too deep, I "awaken" her arms and ears.	No result.
She hears[1] me without my touching her.)	She rises. Comes to me.

[1] "Hears" his thoughts.—*Translator.*

I stop her.	Stands hesitating in the middle of the room.
	Approaches the table.
Extend the arm!	No action.
" " "	She extends the arm.
Lower!	She gropes on one side.
"	She touches the cake and starts.
Take it and give it to me!	She takes it and gives it to me.

She is evidently fatigued; her eyelids droop. "Why," I asked her, "did you take the cake and give it to me?"

"Because all the other objects were *strange*, while the cake seemed to me *well known*. But I did not know it was a cake. I knew only that it was something less repellant than the *strange* objects. I was not sufficiently asleep (active somnambulism.) *My ears should not be awakened.*"

A few minutes later an experience was had, all the more curious because unexpected. I was absorbed in thinking of a matter of personal concern that troubled me the whole day, and despite its intimate nature I must make it known here in order that the reader may understand the occurrence.

The case of Mrs. M. taking up all my time, I neglected several affairs, so that I found myself greatly straitened for money. My attendance on the patient was wholly gratuitous and I did not wish that she should have any suspicion of my embarrassment. As I could not leave her because of the seriousness of her condition (she was constantly subject to fits of suicidal mania) my thoughts were ever returning to the question of finance.

I chatted with the patient pleasantly, but perhaps my voice betrayed my unrest, and I saw that she divined what was in my mind. She halted in the conversation and became pensive. From long-continued observation I too was able to guess the thoughts that occupied *her* mind. After reflection she said to herself: "He is in trouble; he must be helped; but if I am awakened I shall forget all. What shall I do?"

She reflected on the problem and hit upon a plan. She took off a finger ring, as was her custom whenever she desired to remember anything, and her face showed a strong resolution not to forget the meaning of that act.

"You must not think about that," I said.

"If I want to think of it, you will not hinder me"—and she made pretense of not caring about the matter, in order that I might not prevent.

Some minutes later I mentally gave her the order to forget the project. That instant she suddenly withdrew her hand.

"Do not touch me," she said, "for I feel my thought is leaving me."

"It will leave you anyhow," I said, and made a few passes to make her sleep deeper.

"Do not put that out of my head! Oh! you have no pity. What was I thinking of just now? I wished to remember something. I have quite lost it." A few minutes later I noticed on her countenance tokens of renewed mental action. The sleep was become less deep; the thought had come back to her, and again she strove to evade my influence, requesting me to wake her as slowly as possible "for fear of a paroxysm." I awakened her very gently, suggesting cheerful thoughts on her coming out of sleep. Once awake she became pensive and put her hand to her forehead.

"It seems to me," she said, "that there is something I have to remember, but I don't know what." She examined the ring again and again. "No, I do not remember anything."

She was cheerful and talked freely with us.

Here are two more experiments *in the waking state.*

20. What is it I want this moment?	It is true, you want something. She looks round about as if seeking something. Then peering into my eyes, says: "You want a little wine for tea." Correct.
21. And now? (My wish was that she might take a cake.)	No; I know nothing any more; I feel nothing.

December 28.

Endormed in the morning, she recalls her memory of yesterday, and tries once again to fix it in her mind. She finds a new means of doing this. Suddenly she uttered an exclamation—a phrase that could not be understood by us, but which, when recalled at waking, would call up in her mind the plan contrived the evening before. Then, to guard against an influence, she stops her ears and begins to mutter so as not to hear me.

22. I give her mentally the order to forget. She thinks she has won and asks to be awakened slowly. I awaken her. The mnemotechnic phrase is repeated to her. "What does it mean?" I asked. "I do not understand it all," she replied; and she thought no more about it. In the evening she had a slight attack of delirium. She had an hallucination that she was a dead person. The attack ended in a general contracture: this I suppressed. She then fell back upon the cushions and remained motionless.

23. Get up and come to me!	She stirs a little. Result=0.

At this moment she was in very profound sleep (paralytic aideia). She does not hear me unless I touch her.

24. I want you to hear me !	She hears the "noise" of my voice, but does not understand.
25. Ditto. I excite the ears a little by movements of the fingers, which usually produce hyperacusia.	Same imperfect result. I cannot make myself understood. At last, after several minutes, she hears me clearly.
26. I now purposed to make her hear the voice of Miss * * *, which she does not hear of her own accord. (Puységur's experiment.)	Result = 0.
I touch the hand of Miss * * * while she is speaking.	She hears the voice like a whisper, or rather as pretty loud sounds, but not understandable. She hears the voice without my touching Miss * * *. Again I touch Miss * * *, but the patient does not hear the words spoken.

These experiments were probably spoiled by the patient's inconstant and pathological state. After some minutes :

27. Give the other hand ! (I was holding the left).	The right hand stirs. (It was in contracture.)
	She raises it a little.
	She stretches her right hand toward me with much difficulty, "for it is stiff." She gives it to me, then falls back on the pillow very much fatigued.
28. Ask what I want ! (This without touching.)	Result = 0.
What is it ? What do you wish to say ? (Aloud.)	Something urged me to put a question—I don't know what—I have forgotten. Things are all mixed in my head.
29. Open your eyes and awake !	Result = 0.
	She moves her head to right and left, then the right arm, but does not awake.

At this moment she was absorbed by a *somnambulic reverie*, which reduced the sensibility. I tried to awaken her by spoken order, but the result was only a fatiguing drowsiness, and after several minutes I was obliged to have recourse to passes.

December 31.

The patient is feeling well. I produce easily whatever states I wish, and halt at a phase intermediate between lethargy and monoideism. She hears me, but me only, and she cannot answer save by signs or by detached words.

30. Get up, go to your brother, and kiss him !	She gets up.
	Moves toward me, then goes back toward her brother.
	Stops before him, hesitating, goes slowly up to him and kisses him on the forehead with a start.
Why do you start ?	Because it is something *strange*. (She loves her brother dearly.)

There was a serious paroxysm that evening; she gave herself several cuts on the temple with a knife. I came in time to prevent suicide, and endormed her with much difficulty. She did not recognize me. She begged my pardon in somnambulism, at the same time complaining that the knife was not sharp enough.

The normal state did not return till after two hours of sleep. The hysterepileptic seizures do not recur any more, but the paroxysms of mental alienation and the fainting-fits are still frequent.

January 6.

The patient was lying on the couch and heard nothing. I went out noiselessly to make an experiment at a distance.

31. Get up and be seated till I come back !	She frowns, her respiration grows rapid, but she does not move.

The experiment had lasted hardly a minute when it was interrupted. She was not very well, so I gave up the experiment in order to attend to the patient.

January 10.

I endormed the patient by passes at a distance, that is, without touching her. Then I try to

32. Produce deep natural sleep in artificial somnambulism.	Some seconds after the beginning of the mental action, I hear snoring, the lips open and so remain.

A few minutes after, this state ceases. I begin anew.

33. (As above.)	Same signs, *minus* the opening of the mouth.
Open your mouth !	She opens her mouth and sleeps; respiration rapid.
Close your mouth !	No action, probably because her sleep was so deep

She slept well the whole night.

January 11.

State of aideic lethargy, with tendency to contractures.

35. Extend the right arm.	Right arm stirs. Same phenomenon seven times consecutively. Slight movement of left arm. She rises partly. Falls back. Extends the right arm.

At this moment she hears me, but finds difficulty in answering me.

She recognizes an object belonging to me among four like objects, pointing it out as "best known." (She sees it now for the first time, but so she always speaks of what belongs to me, what I have touched, or concentrated my thought upon.) She rejected one object among five that were alike—the object rejected belonged to Miss X., whose presence is to her insupportable. Three different fingers touch her, she recognizes mine; and so on. She asks for a drink, and some one puts a glass of water to her lips; but she notices nothing and keeps asking for a drink. If I hold the glass she recognizes it at once, and drinks with pleasure. (This phenomenon is of daily occurrence.)

January 14.

Mrs. M. falls asleep with difficulty, but her sleep is exceedingly deep. Even after half-an-hour she does not hear me. There is no contracture. The head is not very hot. The members are not cold. The pulse is pretty regular, 80 pulsations. From time to time some slight tremor of the fingers. The nervomuscular superexcitability does not exist. The members retain the posture given them. Consequently there is a state of cataleptic aideia.

36. I wish you to hear me.	No action. A minute later several fainting spells.

Because of the pathological state, no conclusion is to be drawn from this check in the state of cataleptic aideia. Little by little she passes of her own accord into the *somnambulic delirium.* An hour later, acting more powerfully, I brought about a calm somnambulism.

37. Sleep well the whole night!	She does sleep well the whole night.

She awakes quite well, barring an amblyopy that soon passed away.

January 18.

The improvement in Mrs. M.'s health permits me to make a few new experiments. I endorm her as usual. Then I endormed her brother also, and he remained motionless in an armchair in the middle of the room. He was in a state of mild paralytic aideia, easily effaced, but from which he could not come out by himself. Mrs. M.

lay on the couch at the lower end of the room, in passive somnambulism. By means of a few passes I put her into a deeper sleep—a little too deep even—and I withdraw to begin the experiments.

38. I order her mentally to kneel in the middle of the room.	Result = 0.
	She stirs. (Afterward she said that she was sleeping very well, when something awakened her.)
	She gets up and walks toward the middle of the room, where she encounters her brother. This time she does not start at all; on the contrary, she feels of him with a certain satisfaction and a little astonishment.
I take hold of her hand.	Then she goes back to the couch and sits down.
Kneel!	After two minutes of hesitation she kneels.

She told us afterward that it was her brother that had put her "off the scent." "I knew not what to do," she said; "I sensed you here and there. That confused me. There was 'another you' in the middle of the chamber."

"'Another me?' How is that?"

"Something that was you. I don't know. But that confused me."

January 24.

She was put to sleep in the armchair (*aideia*, then *monoideism*).

39. Ordered to blow out a lighted wax candle on the piano.	She rises.
She stands so near to the candle that I blow it out myself, lest her gown take fire.	Comes toward me, then goes toward the piano.
	Touches the music as she gropes.
Give me the candle.	Removes the candlestick.
	Takes the candle out of the candlestick and brings it to me.
40. Give me your left hand! (I held her right.)	Raises the left hand and gives it to me.
41. Come to me.	Frowns.
(This experiment was performed with many precautions; the somnambule was not aware that I had retired and was acting, at a distance of several yards, from the rear end of the hallway.)	She rises.
	Extends the right arm, advances, opens the door, and goes straight into the hallway, where I hasten to meet her.
	She showed pleasure in encountering my hand, then she returned slowly to the drawing-room.

That same evening I made two experiments more, to test my personal magnetic action.

As I have already said, whenever the patient touched a "strange" object or person, *i. e.*, outside of my influence, there was a start and an instinctive repulsion. This I wished to verify. I requested her brother to take, unnoticed by her, a seat not far from her, a little behind where she was. Then, by exerting an attractive action upon her arm, I so guided her that she by chance touched the arm of her brother. There was a shudder of repulsion, and a repetition of the experiment gave the same result. Then I endormed the brother, unknown to the subject, where he sat, and began the attraction again. She was obliged to touch her brother several times, *but no more repulsion was shown.*

Another comparative experiment was made during normal sleep. Three hands, of three different persons, were brought within a few inches of her head. After a minute she became slightly agitated, raised her hand above her head, as feeling for something, pushed away the other two hands, and drew mine to her. Almost immediately the natural sleep was transformed into somnambulism. Not knowing that I was there, she was astonished to see me near her

February 4.

On awaking she showed, as usual, her sensibility with regard to the psychic state of those present. "I am very angry at Marie," she said. "Why so?" "Because all the time she has been trying to keep me, and it is absolutely necessary for me to go." (That was exactly so.)

February 5.

The hysterogenic point beneath the left clavicle no longer exists. But she does not yet feel the warmth of my hand at the back of the head (delirogenic point). In somnambulism, her sensibility is already normal. Magnetization checks the beginning of a paroxysm of delirium. Aideia, 82 pulsations. After thirty minutes of this state the head grows cooler. A few minutes later passive somnambulism appears, and then active somnambulism. Then she asks me to awaken "her whole body except the front of the head." In this state she manifests a very high degree of sensibility. She notices everything, but feels a difficulty in reflecting. *If one pinch me, or strike me, it hurts her.* She describes perfectly my mental state, or rather my sensations. The touch of a stranger is still disagreeable to her. I give myself a pinch. "I do not like that," she said.

In general she is not obedient in this state, in spite of the transmission of sensations; she is too irascible for that. She undergoes the influence of my sensations, but not of my will. The memory persists.

After an hour this state disappears and she falls into her normal sleep.

Here I stop. The history of this patient has been most instructive to me. I have with regard to her case a great volume of notes taken on the spot, and having a bearing upon sundry other questions, among which the question of therapeutic holds the foremost place. Next comes the question of mental suggestion, that of physical action, that of hypnotic phases, and a few others of less importance. I have purposely left out whatever was not directly concerned with psychic transmission, so as not to complicate the task of the reader, who will find here quite enough if he will but study with the necessary attention the details given above.

I have left out nothing—quite the reverse—that had to do with our principal subject. I have given *all* the experiments, even those which of necessity had to be inconclusive and resultless, or which could be successful only in part, because of accidental circumstances. Hence, the general effect of this narrative will be less conclusive for the reader than for myself. As for me, I am free to confess it, these experiments were decisive. At last I have the *personal impression* I sought so long, of a true, direct, indubitable action. I was fully sure that there was neither chance, coincidence, nor suggestion by attitude or gesture, nor any other possible cause of error. Wherever these influences were for a moment added, I have pointed them out, and the reader will himself be able to appreciate them in accordance with the principles already set forth. But a point that may have escaped the reader, just because of the strictly objective manner of this account, is that from the second week forward I was already master of the phenomenon, and that if in the subsequent experiments there still were checks, that was solely because I wished to verify the impossibility or difficulty of success in certain hypnotic phases. Whenever I produced the phase of sleep favorable to these experiments, they were always successful. The reader will not wonder that I was delighted with this discovery. For me, a phenomenon is not a scientific fact if one is obliged to accept it purely and simply as an accident distinctly seen, clearly controlled, but which has come about one knows not how, and which is not repeated one knows not why.

And that was just the case with all the experiments in mental suggestion hitherto known, even with those cited in the first two chapters, and which so astonished me. Mr. D. divined several letters, and even whole words, one after another, under pretty stringent conditions. But what annoyed me was that after a series of amazing successes, there were other series in which the transmission seemed absolutely in default. And yet the subject kept on divining, and divined amiss, wholly amiss. Why? I could not tell; but this inconstancy of the phenomenon discredited in my eyes results the most astonishing. This all the more that on some occasions I succeeded in mentally representing to myself the object with great

distinctness. For example, I represent to myself a *lamp*, and I almost see it flaring before the eyes of my imagination.

"It is a *book*," says the subject. Seeing that I do not confirm this conjecture, "No," says he, "it is a cigar."

Is not that enough to disconcert a skeptic, particularly one but little prepossessed?

Well, I now understood this unevenness, this inconstancy of phenomena: Direct mental suggestion is possible only in one state, and that a transition state between two others. Though I was able to fix that state for a few moments, by graduating the sleep almost at will, that was not possible to do in the waking state, wherein each moment brings *change*, without which, as Bain very well says, there is no consciousness, and wherein this change, as such, is not appreciable for the subject. Thus it sometimes happened that Mr. D. would say to me: "I feel well disposed to-day." Yet the experiments would be unsuccessful, while on another day they would proceed far better, despite his untoward presentiments.

All was now comparatively clear to me; we must regard thought-transference as a sort of *audition*.

One does not hear who is deaf; one does not hear when there is too much noise; one does not hear when one is absorbed in thought.

One is deaf to a transference of thought when one sleeps so soundly that the brain does not perform its functions. How, think you, can a subject sunk in *profound paralytic aideia* obey your thought if he cannot even hear the living voice? He is deaf. In vain will you shout into his ear, *a fortiori* in vain will you whisper to him from a distance. Hence mental suggestions are still more difficult in this state of profound aideia than in the waking state, and therefore those who think that all that is needed in order to make one amenable to their mental action is to put one into the magnetic sleep, are mistaken.

One does not hear when there is too much noise, and a *hypnotized* subject will not "hear" your thought because he is at the mercy of everybody; because he has too many strong and different sensations; because his attention is not directed solely to you. Consequently, even though you were to make him hyperæsthesic in every possible way by fixing the gaze on a shining object, or other inanimate object, you will not make him easily sensitive to exceedingly slight *personal* influences, such as thought-action.

One does not hear when one's mind is occupied by other thoughts, because the one action excludes the other. One that is talking hears badly. The dreams of *active somnambulism* being more vivid than those of normal sleep and being nearly always "spoken" dreams, are more opposed to delicate perception than is the waking state itself. Consequently, it is useless to attempt direct mental suggestion with a somnambule that is talking with vivacity, or who is carrying out any

somnambulic project whatsoever; he will not hear you. His attention is not null, as in an hypnotized subject; but what is worse for your purpose, it is turned in another direction. Hence, despite the favorable appearances—for he can always hear you, his magnetizer—the state of *strongly active polyideia* is no better for experimental purposes than that of paralytic aideia.

Then, as regards the intermediate states: Some subjects who are capable of presenting these two opposite states—aideia and polyideia—do not pass directly, or at least may not pass directly, from the one into the other. They tarry for a longer or a shorter time in the *monoideic* phase. You have before you no longer an inertia, a complete paralysis of the brain; neither have you a reasoning activity more or less like that of the waking state; but you have to do with a brain that concentrates all its functional action, and that cannot but concentrate it, upon a single idea standing alone and dominant. It is dominant, not being counterbalanced by any other thought. It is hallucinational for the same reason and through the vivacity, the physiological vitality, of a brain that has just rested itself better than usually (aideia), and which asks only a chance to work. Hence you need but little to set it a-going. A nothing moves it, a nothing controls.

That is the moment for suggestions. Mental suggestions? Yes and no! This state is still far more complex than it seems to be. The monoideic state, in the first place, may be two-fold—*active* or *passive*.

When active, it approaches polyideism while remaining what it is. It is akin to it by a very great preponderance of one idea *associated with a few others that are very faint.* This is the state of *somnambulic monomania*. The subordinate ideas belong to the real world, the dominant one to imagination. Consequently the subject cannot make his way so well amid the surroundings of actual life as can an active somnambule proper, who reflects, perceives, shuns obstacles, and performs a difficult task. But if he sees (imperfectly) any object, his dream may easily persuade him to believe it a book, a lantern, or a bird, and then he will do a certain number of acts meet to such vision.

This state, the state of spontaneous hallucination, is no more favorable to thought-transference than is active polyideism, whereof it is only a lower grade as regards lucidity, but more advanced and more isolated as regards liveliness of sensations.

Passive monoideism, on the other hand, comes nearer to aideia, just because of its character of passivity, inertia. The vividness of sensations is the same. But *they can no longer arise of their own accord;* they must be suggested, and they are suggested with the utmost ease. Whatever you say is law to the subject. He is under obligation to divine as you bid him, and the divination is done, not by reflection, but by unconscious, imperceptible associations which deceive you,

which appear and disappear almost before their task is done. For this state is, so to speak, still more monoideic than the preceding one. The faint, accessory ideas are almost entirely wanting. And it is always a state of tension, even violent tension, like the other, with this difference, that the tension of active monoideism comes into play of itself, while the tension of passive monoideism always awaits an external stimulus however slight—a breath, a hint, a nothing. Bain would say that it is an "involuntary energy" requiring only an impulsion to show itself.

Is this the phase for mental suggestions? Almost! Anyway, mental suggestions *always act* in this phase, that is to say, you have only to concentrate your thought strongly and the subject will perceive it. There will be first a corrugation of the eyebrows, an expression of attention in the countenance, an agitation of the members, and at last a doing of your will, or a beginning of doing it. One thing, however, may mar the experiment: if your action is too lively in the beginning, or if it is too vividly (albeit indistinctly) perceived by the subject, it will have upon him an awakening influence—awakening in the relative meaning of the word, viz., the subject, though he executes your mental order, and because of the same, will pass too quickly into a state of sleep a little less deep, into *active monoideism*, and then will be all eagerness to execute your mental order without having grasped it fairly; he will seek you, will run after you, and will even "insensibilize" himself[1] by this involuntarily suggested monomania. Or else he will pass into a state of sleep still less profound, more tranquil, and at the same time more lucid, a state of *active polyideism;* he will begin to divine, to guess by his own reflection what he can no longer perceive passively, and then he will be capable of doing other things than you have ordered. Finally—and this happens seldomer, but does happen with subjects that are too sensitive—the mental impulse you give him produces first excitation, after the manner of narcotics, and then puts him to sleep; and the subject, after making a beginning of carrying out the order, lapses into complete aideia. Thus this state does not afford us the best guaranty of success; for that we must seek a little deeper.

The true moment for mental suggestion is *the state betwixt aideia and passive monoideism.*

But if that is so, and if our experiment has a better chance here than in outright passive monoideism, the cause is simply that it has more time at its command, and that one usually makes too great an effort in beginning the mental action—a thing helpful this side the threshold of aideia, while beyond that it is not safe. Could we be certain which stage we had before us, we should have only to conform

[1] *S' insensibilisera!* that is, *will make* himself insensible [to your further action]. —*Translator.*

to its requirements; we would act with some forcefulness in aideia (to awaken the brain), a little more gently in monoideia (not to awaken it too much), and we should have free scope up to the very limits of both states. In any case the brain should be "regulated;" it should be regulated for *nascent monoideia.* Permit me to illustrate by a comparison with the telephone.

A telephone, unless it is well regulated, does not reproduce distinctly speech at a distance. But in telephony, as in neurology, all is relative. A telephone is well regulated when the vibrating disk is very nigh, but not too nigh, the magnetic core of the coil; you may then shout pretty loud without impairing the distinctness of the sounds transmitted. On the contrary, the louder you shout the better they hear at the other station. And they would hear better still, comparatively, were the disk still nigher the core, almost touching; but then, in speaking too loud there is danger of the disk sticking to the magnet and of almost complete failure to transmit. *Medium regulation bordering on maximum* is what practice requires, herein differing slightly from theory.

But how "regulate" a somnambule? Ah, that is the question! Fortunately, it is not much more difficult in hypnology than is that other question in telephony; only here as there the instrument must be *regulable.*

Subjects there are who will not be controlled in this respect; they can be employed for other purposes, or with them one has to be content with a hurried mental action, as has been done hitherto. But we must also eschew subjects that are too obedient and already trained—subjects worked by turning a crank, so to speak. But again one must learn how to bring about the degree of slumber that is needed. The first seances, however, must have for their one end purely passive observation of the effect produced by your action, *in order to learn what kind of a subject you have.* You shall spend hours, if needful, waiting for the subject to awake of his own accord, unless he asks to be awakened sooner. In subjects that are specially susceptible of sleep—for some there are with whom you can make all the physical experiments, but not the psychical—you will produce two principal phases, namely, the *deep sleep*, which vanishes by degrees, and the *lucid sleep*, or somnambulism proper. What you need is an intermediate state. The subject must not be allowed to become too much awake and to regain his spontaneous activity, nor is he to be put in too deep a sleep, for then he will not hear you. The best means to obtain this graduation is by *magnetic passes*, so-called, up-and-down and crosswise, for the depth of the slumber usually increases with the number of those, and lessens with the number of these. By making two, three, four passes right before the subject (without contact) you obtain a little less or a little more of sleep, and sometimes

one is able to graduate at will the intermediate phases just mentioned. Should such graduation by passes be impossible, you will have difficulty in obtaining that result by any other means. And above all one must be careful not to employ different means for the different phases, for so one establishes an artificial ideorganic association, a bad habit that will disorganize the subject.

It is understood that I do not enter here upon a discussion of the action of the passes. One may suppose that they exercise a physical action, or one purely suggestive : that is of no importance for the end in view. I simply mention the oldest and best known process, which gives the most constant and most beneficial results as regards the subject (certain hypnotic processes are harmful) and which serves best to graduate the sleep at will whenever graduation is possible.

Once master of your subject, you have only to avail yourself of the moment when *he hears you and does not yet give answer well.*

Do not mistake difficulty of speaking, caused by a contracture of the voice-muscles, for an aphasic difficulty, *i. e.*, one of purely cerebral origin. The latter is what you require.

We will enter on some further details when we state the conclusions of our study.

CHAPTER IV.

EXPERIMENTS AT HAVRE.

IN the month of November, 1885, Mr. Paul Janet, of the Institute, read to the Society of Physiological Psychology a communication from his nephew, Mr. Peter Janet, professor of philosophy in the Lyceum at Havre, entitled " Upon Some Phenomena of Somnambulism." This title, prudently vague, veiled some quite extraordinary revelations. The subject was a series of experiments, made by Messrs. Gibert and Janet, that seemed to prove not only mental suggestion in general but also mental suggestion from a distance of some kilometers, and unbeknown to the subject.

That I followed the reading of this communication with interest was matter of course: everybody did the same, not without a good measure of incredulity. Mr. Janet abstained entirely from theorizing; he simply stated the facts, and left them to be believed or not. The communication, listened to in silence, was passed in silence, save that a few exceptions, of a very general character, were taken by our President, Mr. Charcot. Positively there was no ground for argument, but one might examine the facts. Having decided to do this, I took the first favorable opportunity to carry out my purpose.

True, I had already made many experiments in mental suggestion,

and on that point I no longer had any doubt: I must needs surrender to evidence. But the facts recounted by Messrs. Janet and Gibert presented quite another character. These gentlemen carried out no experiments like those we have been observing in the case of Mrs. D. in the waking state and of Mrs. M. in the state of sleep; they tried, but without success; whereas they did attain success under more extraordinary conditions, giving mental suggestions to be carried out much later, and endorming their subject at a distance.

To me this seemed noteworthy. I wished, first of all, to verify this latter phenomenon, recognizing its importance for a theory of suggestion and for the problem of magnetism in general. It was evident that such verification would be the death of the exclusive theory of contemporary hypnotism, which was boasting itself to be the legitimate successor of animal magnetism, deceased, and destined henceforward to take a very modest place alongside its predecessor. On the other hand, should Messrs. Gibert and Janet have been duped by any illusion, we must once again retrace our steps to see if even suggestion from anear be not due to some presently incomprehensible exaltation of the perceiving mind, and not to thought-transference in the true sense of the word.

The subject of these experiments was Mrs. B., a countrywoman of Normandy, 50 years old, in good health, honest, very timid, intelligent, but quite uneducated (she cannot even write and can hardly read). She is of robust, sturdy constitution; when young was hysterical, but was cured by an unknown magnetizer. Since, only in somnambulism do some traces of hysteria appear, when she is crossed. In the normal state, the hysteria has disappeared, but the hypnotic sensibility that served as its ground persists, as usual. Mrs. B., ever since childhood, has been subject to natural somnambulism, in which she recounts the singular hallucinations she experiences. The somnambulism recurs more frequently of late. The woman has a husband and children, who enjoy good health. Several physicians have, it seems, wished to experiment with her, but she has always rejected their propositions. Only at the request of Mr. Gibert did she consent to spend a little time in Havre. She is endormed very easily: one need but take her hand, grasping it gently for a few moments, *intending to endorm her;* otherwise there is no result. After a longer or shorter time—2 to 5 minutes, *according to the person that puts her asleep*—her look becomes vague, the eyelids quiver with slight motions that often are very rapid, till the eyeball hides itself behind the lids. At the same time the chest rises laboredly: the subject is evidently ill at ease. Very often a shiver agitates the body for an instant, then she gives a deep sigh and throws herself backward, plunged in deep sleep.

Hypnoscopic exp.: anæsthesia, *general* contracture almost instantaneous, *deep sleep.*

I reached Havre August 21, and found Messrs. Gibert and Janet so convinced of the reality of the action at a distance that they willingly assented to the minute precautions suggested to them by me so that I might be able to test the phenomenon.

Mr. F. Myers and Dr. Myers (members of the London Society for Psychical Research), Mr. Marillier (of the *Société de Psychologie Physiologique*), and myself, formed a sort of commission, and the details of all the experiments were arranged by us with common accord.

The precautions we observed in experimenting were as follows:

1. The precise hour for the action at a distance was fixed by lot.

2. It was not made known to Mr. Gibert till a few minutes before it arrived, and forthwith the members of the commission went to the pavilion.

3. Neither the subject, nor any occupant of the pavilion,[1] distant nearly a kilometer, knew the precise hour, or even the kind of experiment that was about to take place.

4. To avoid involuntary suggestion, neither we nor any of those gentlemen entered the pavilion except to verify the sleep.

First Experiment.—Dr. Gibert must endorm the subject from his office, 51 St. Quentin Street, and mentally order her to go out into the street. Action begins 5:50 P. M. Probable time of executing the order, 6:05.

At 6 o'clock precisely we reach No. 5 Ferme Street, where the pavilion is, but we stand aloof, so that no one might suspect our presence. We wait a quarter of an hour in vain; the subject does not come down into the street. Consequently the experiment was a failure in that respect.

We enter the pavilion, ringing the bell at the garden gate, and go up to the first floor, but find no one there.

Two of us go down to the kitchen, on pretext of inquiring whether Mr. Gibert has yet arrived, and find the subject sitting motionless but *awake*. We pass to a chamber on the first floor, and there talk about the experiment, which we regard as abortive. A few minutes thereafter the subject enters the parlor (opposite to the room we were in), and there we find her reclining on an easy chair in *lethargy*. That, it seems, is always the case when she is endormed by Mr. Gibert. Dr. Gibert is at this moment making his professional calls, and cannot join us.

The subject makes answer to questions put by Mr. Janet, who of late has been endorming her more often than Mr. Gibert.

Mrs. B., in somnambulism, tells of how toward six o'clock she felt ill at ease, and was about to go to sleep when a ring of the bell awakened her, and she took refuge in the kitchen; how thereafter she

[1] *Pavillon:* the house at which the subject lodged.

was unable to overcome the drowsiness, and so went up to the parlor. "'Twas Mr. Gibert played me that trick," she added; "you torment me; I don't want folks to endorm me without giving me notice!"

We profit by the somnambulism to make some experiments, which the subject interrupts continually, asking "Where is Mr. Gibert? Where is he? I must go and look for him." She tries to get away from us and go into the street. We hold her back.

After an hour we withdraw, and Mr. Janet awakens her. She recollects nothing, but she has headache, and at evening we go away; she is all the time restless, falls of her own accord into somnambulism, and goes down into the garden seeking Mr. Gibert. They hold her back with difficulty, and send for Mr. Gibert, who comes and quiets her.

Despite these unfavorable conditions, another experiment was arranged, to come off at 12:15 that night. Mrs. B. was sure to be then in her natural sleep.

Second experiment.—"From a distance to make Mrs. B. pass from her natural sleep into somnambulism and go find Mr. Gibert in his office in St. Quentin Street."

The success of this experiment, even according to those gentlemen, was hardly probable. Besides, this was the first time they ever tried to act during the subject's natural sleep. So it failed; the somnambule did not come down stairs; and, as we did not wish to disturb the inmates of the house, we did not go in to see whether there were any indications of action. So much at least is certain, that Mrs. B. did not leave her chamber. The only difference noticed in her behavior on this day as compared with other days was, that instead of rising very early as her custom was, she slept till after ten o'clock, and she got up with a headache. She went down to the kitchen and set herself to work, but, the headache continuing, she went again up to her chamber toward noon.

Then came the *third experiment.* Mr. Gibert was to endorm Mrs. B. from his own house at 10 minutes before 12 o'clock, exerting mental action during 10 minutes. Mrs. B. was to be endormed and to remain in the parlor. At 12.07 we reach the pavilion without ringing the bell, and taking care to make no noise. Mrs. B. is still in her chamber. So as not to influence her by our presence, we send the cook to her to ask if she is coming down to breakfast.

Mrs. B. is walking briskly up and down the room. "I am in a queer way," says she to the cook; "I don't know what ails me. I am trembling; but I will go down all the same."

She did not come down till 10 minutes afterwards. We watch her from a distance. She is not quite endormed, but neither is she in her normal state. She seems not to see what is going on around her nor

to know what she wishes to do. She enters one room and then another; a minute later she falls into *lethargy*.

The same questions, the same answers. "Again it is Mr. Gibert that plays this trick upon me. But I have made you wait (smiling). *I have had time to dip my hands in water*, and that kept me up for some time. But where is Mr. Gibert? Why does he not come? Why torment me so? I must go and look for him (applying both hands to her forehead). No; he does not want me to go in search of him (fretfully). Why doesn't he wish me to go?"

Sundry experiments are made, in the course of which I remove her headache.

Mrs. B. recognized all the persons present by touching their thumb, and particularly by scratching lightly the thumb nail. There was no getting an explanation of this trick, which to her seemed quite natural. She would not even tell us how she hit upon it. I can only say that in this way she perceives really the personality, the physical state, sometimes also the mental state of people. After touching my thumb she declared that I should have great influence over her and that I might easily control her. "For example, I should not dare to say *no* to you," said she; and so on.

Thenceforward she seems really to feel my presence, and to be subject to a sort of attraction for me. Wishing to test the reality of this influence, I concentrate my thought and order her to give me her hand; suddenly I see her start; she grows excited, leans toward me, and holds her hand out to me. Thrice I made this experiment with the same success while she was in a state more or less proximate to monoideism. When she was in the *aideic state* the effect was null, retarded, or incomplete; she became agitated, but did not execute the mental order.

In *active somnambulism* the experiments were sometimes successful, if I took care to select a moment of inaction. In acting while she talked animatedly with Mr. Janet or another person, or when she was absorbed in her own thoughts, I obtained no result, absolutely none. I had also occasion to notice that too great concentration of my own thought rather marred the result of the experiment; it upset her, producing spasms and general tension, interfering with the exactness of the transmission. On the other hand, a thought formulated with precision but, so to speak, in passing and without special mental pressure, produced an action whenever the subject was amenable to those mysterious influences. Here are two experiments made under this condition of tension, which were unsuccessful.

I was at the lower end of the room, hid behind Mr. Janet, and I ordered the somnambule to kneel. She manifested strong agitation, seemed to be looking for me, her eyes opened and remained open without intelligence. The state in which she was at this moment was

like that produced by Donato when he makes his subject follow him. It was thus a state of fascination, with a noteworthy difference, however. The state of fascination is a monoideic state. It is passive, eminently passive, when you hold the subject fast with your eye, operating upon him as you please. This state is sensitive to visual influences, to the imitation of gestures, etc., when it is calm. If, on the contrary, the subject, drawn by your eye, follows you, the calm disappears, a sort of fever seizes him, his thought is too absorbed, too tense in one direction to allow new influences to act; the subject follows you madly, he is infuriated by the slightest obstacle, and then he can do nothing but follow your eye with blind obstinacy. That is not passive monoideia, it is active monoideia, *hypnotic monomania.*

Acting mentally at a distance and unseen by the subject, I produced a state like this, but more agitated and less clearly defined, less fixed, the fixity of gaze being lacking as a support to the monomanial tendency of the subject. She was, therefore, upset, agitated, attracted, but indistinctly, and her mental state, which asked only to be dominated by one thought, was at the same time too much on the strain to grasp it. It was an almost aideic fever, because of the mingling of indistinct ideas.

The subject began with rising to her feet; then I thought I noticed a bending of her body as though she were about to kneel; but this movement ceased and Mrs. B. straightened herself and for a moment remained standing. Then I changed my thought and ordered her to come to me and then to go upon her knees before the easy chair. She stepped tottering toward the chair. At that moment I pronounced mentally the words "Kneel!" "On the floor!" The latter expression caused me some uneasiness and I regretted it. "Perhaps she will fall to the floor and hurt herself," I thought; so I began anew the mental order, "Kneel!"

At that instant Mrs. B. fell backward in lethargy into the arms of Mr. Janet.

Another experiment, suggested by Mr. Frederic Myers, also failed, The somnambule was to take in her hands a cushion placed to the left of her on the couch. This experiment took a good deal of time, for the different states of the subject succeeded one another rapidly. At times there was no action; at times the feverish monomanial agitation interfered with the distinctness of the transmission. Mrs. B. stretched her arms forth toward the cushion, but did not take hold of it. At last she rose, went to the end of the couch where the cushion was, paying no attention to it, and *went down upon her knees*—thus executing the order she had failed to execute when given before, *and which I was not then thinking of.*

But, I must add, there is no certainty that in this case we have a retarded mental perception of the first order; for, inasmuch as I

considered the first experiment a failure, I said to the gentlemen present that I had chosen that injunction rather than another, expressly because it had not succeeded definitely with my former subject. At that moment the somnambule was in lethargic aideia and could not hear us; but we must never trust this hypnotic deafness, for though it is absolute as regards reflex action, it may be that it does not exclude latent, unconscious audition, and this may manifest itself in a subsequent state. I may even say, I think, that the habitual overlooking of this fact by experimenters does a great deal toward making their observations inexact.

Finally, a third trial, in which she was ordered to give her right hand while I was on her left, was only in part successful. There was a motion of the right arm in the direction of me, but the hand was not given.

It is to be remarked that all these experiments were made by me without my touching the subject, who never was magnetized by me. She was at this moment under the influence of Mr Gibert (absent), and of Mr. Janet, who awakened her at length, not without difficulty

Fourth Experiment.—On account of the patient's fatigue, it was about decided to suspend experiment till the morrow; but not being satisfied with the first three, I urged Mr. Gibert to allow an immediate repetition of the second, which had failed (Cagliostro's experiment—endorming the subject from a distance and making her come to him across the city).

It was half-past 8 in the evening. Mr. Gibert consented. The precise time was chosen by lot. The mental action was to begin 5 minutes before 9 and to continue till 9.10. At that moment there was no one in the pavilion, besides the subject, but the cook, and she did not expect that anything was to be done by us. No one went to the pavilion. Profiting by this absence, the two women went to the parlor, and amused themselves with playing on the piano.

We reached the neighborhood of the pavilion past 9 o'clock. Silence. The street was deserted. Without making the least noise, we broke up into two parties to watch the house from a distance.

At 9.25 I saw a shadow appear at the garden gate. It was she. I hid in a corner to listen without being observed. But I heard nothing. The somnambule, after waiting a minute at the gate, went back into the garden. (At this moment Mr. Gibert was no longer acting; by dint of concentrating his thought he had a sort of syncope or stupor, lasting till 9.35.)

At 9.30 the somnambule appeared again at the gate, and this time sprang into the street unhesitating. She hurried along like one who is late, but who must positively reach his destination. The other gentlemen, who were on her route, had no time to notify us—Dr.

Myers and me ; but, hearing rapid footfalls, we followed the somnambule, who noticed nothing around her ; or, at least, did not recognize us. Reaching Du Bard Street she began to stagger, halted a moment, and came near falling. Suddenly she started forward again at a rapid pace. It was now 9.35. (At this moment Mr. Gibert, come to himself, began the action again.) The somnambule hurried on regardless of surroundings.

In ten minutes we were quite near Mr. Gibert's house, when he, thinking the experiment had missed, and wondering because he did not see us back again, steps out to meet us. He comes across the somnambule, who keeps her eyes still closed. She does not recognize him. Absorbed in her hypnotic monomania, she rushes to the staircase, followed by us all. Mr. Gibert wanted to enter his office, but I take him by the hand and lead him to a room opposite. The somnambule, highly wrought up, looks for him everywhere, brushing by us, but not noticing anything. She enters the office, feels of the furniture, repeating in a tone of distress, "Where is he? Where is Mr. Gibert?"

Meanwhile the magnetizer was seated, making not the least motion. The subject enters the room, almost touches him as she passes, but in her excitement fails to recognize him. Again she rushes through other rooms. Then the thought occurred to Mr. Gibert to draw her to him mentally, and in consequence of that act of will, or by simple coincidence, she retraced her steps and seized him by the hands.

That moment an insane joy took possession of her. She springs upon the sofa, claps her hands like a child, and cries, "There you are! There you are at last! How happy I am!"

Then she repeats to us her impressions. The two women, Mrs. B. and the cook, were amusing themselves in the parlor, playing and singing, profiting by the absence of the lady of the house. Then, toward 9 o'clock—9 *o'clock*, she said, *lacking two or three minutes*,[1] "being seated on the sofa, I felt a drowsiness coming upon me." "It was you," said she, addressing Mr. Gibert, "that did that to me. I knew these gentlemen were waiting in the street. 'Well,' said I to myself, 'let them wait ; I have enough of this nonsense.' But I could not make a long resistance, and I ran like a crazy woman."

She was able to name the streets she had traversed, but she had "met nobody."

The evening was a very interesting one. After enjoying for a good half-hour the presence of her "dear Mr. Gibert," and felt of the thumb of Mr. Janet, whom she also "loves dearly," she suddenly exclaimed: "And that gentleman—the other gentleman—what's his name? Where is he?" She reaches forth her hand in the direction of me, groping in the air. I give her my hand. She examines my

[1] But according to the cook the parlor clock pointed to 9.15.

thumb after her own fashion, recognizes me[1] with satisfaction, but continues the examination. "What, then, is your name? Mr. Oko—Goro—I don't know." I repeat, mentally, my name, but she cannot yet speak it.

"You are—you are not English. [The first day she took me for Mr. Frederic Myers, which proves that she did not *see* persons.] You are from Paris—but you are not French; you have come only for France—you are from—— What is the name of your country? Bre—— No! Po—— Poland, isn't that it? You endorm many, a good many people. Why? I don't want you to endorm so many people. Listen! What do you do in Paris? [She applies her fingers to her forehead.] A factory, you make ape—apa— how do you call it? Apparatus, isn't that it?"

"What are those apparatus used for?" asked Mr. Gibert.

I thought of telephones, but what came into her mind was the hypnoscope (she had seen one in my hands, but she has never seen a telephone).

"Oh, it works so." Here she imitated general contracture—a reminiscence of yesterday's experiment.

We pass to other experiments, but the somnambule's thoughts are elsewhere, she is preoccupied about me. In vain do I hold my tongue, withdraw, hide; she seems always drawn toward me, and wants to go and find me. She grows angry at Mr. Janet, and says he (mentally) forbids her to keep her thoughts fixed upon me.

Seeing this strange influence, Mr. Gibert proposed that I should take his place, judging that I could obtain results still more remarkable. But I decline. "It is a sympathy," I said, "a somnambulic passion such as we sometimes see, rather than a really stronger influence. I do not know the subject well enough, and, besides, in delicate experiments it is not well to multiply influences. I trust more your conversance with the subject than my personal power. Finally, inasmuch as it is a question of facts that I have not yet verified, and which I am trying to study, I prefer to retain my independence as an observer."

Consequently, Mr. Gibert was requested to continue the experiments and in particular to attempt *transmission of sensations.*

To the end that the attraction that my presence seemed to exert upon Mrs. B. might not become a hindrance, I asked Mr. Janet to suggest to her the thought that I was gone away.

"Mr. Ochorowicz is gone; he will not return. I forbid you to think of him!"

This order, several times repeated in view of the opposition made by the subject, secured for us a quiet time for nearly an hour. During that time she spoke no more of me and I was able to stand quite near her and to watch the experiments.

[1] That is, recognizes that I am the one whose power she lauded.

It was necessary to select the favorable moment for the transmission of sensations, for that phenomenon, as well as mental suggestion in general, succeeds only in an intermediate state betwixt aideic lethargy and regular monoideism. I was glad to be able to verify in this remarkable subject the same *physiological conditions* which were first formulated by me before the Society of Physiological Psychology, January 25, 1886, and which were based upon a detailed study of the phenomena presented by Mrs. M.

Verification of the state needful for transmission was made in the following manner: Mr. Gibert drank slowly alongside Mrs. M. a glass of water. Immediately she exhibited the movements of swallowing.

After this preparatory trial, Mr. Gibert, followed by Mr. Marillier, retired to a remote apartment. On the threshold of the chamber I whisper in the ear of Mr. Marillier: "Pinch his right hand."

Two minutes after, Mrs. B. manifests the signs of suffering sharp pain. Both her hands, but the right in particular, are in a quiver. "Don't," she cried. "Don't do that, wretch."

The second experiment was proposed in writing: "Puncture the middle of his forehead."

In the subject, general agitation, less marked in the arms. The somnambule raises her hands toward her forehead, complaining of the hurt they are causing her, and continually repeating: "You wretch! Don't do that! Wretch!" Her agitation continued for a minute after the return of the two gentlemen.

Then came the last experiment—one that I had never witnessed before—namely, mentally to order an act that was not to be performed till the following morning. At the stroke of 11 o'clock Mrs. B. *was to go to the parlor*, take up a photograph album that lay on the table, open it and examine the portraits. (This order was proposed in writing by Mr. Frederic Myers.)

To communicate the order mentally, Mr. Gibert seized Mrs. B.'s hands and applied his forehead to her's. I stood quite close to them: he made no movement of the lips. He merely attracted the subject's attention by saying, "Listen, Léonie!"

At the moment of transmission Mrs. B's countenance assumed a peculiar expression; one would say she was listening with all her powers of attention. But at the same time it was plain that Mr. Gibert did not act auditive sensations for her,[1] for while still retaining this expression she began to be agitated, to writhe in strong convulsions. There was a true paroxysm of hysterepilepsy, with grinding of the teeth, clonic movements and contractures. After barely two minutes the communication was at an end, and Mrs. B. grew quiet little by little, giving no sign that she knew what had passed.

[1] *N'agissait pas pour elle des sensations auditives.*

Messrs. Gibert and Janet even assured me that she could not tell what was asked of her, *and that orders given in this way to be carried out in the sleep itself had never succeeded.* Hence, it appears that this is a transmission eminently *unconscious*, and that the subject's unconscious requires a certain time to crystallize, so to speak, the impressions received, and to excite the corresponding muscles.

This phenomenon is not an isolated one in psychology. It sometimes happens to one, as he lies abed, that the thought of getting up comes to him, but without sufficient force to overcome his indolence. This thought returns once or twice without result. Then, while his mind is occupied with quite other things, he feels himself raised suddenly, as by a stranger force, and is up with a bound without making up his mind to act.

So, with regard to waking at a set hour. I must take the train very early. I know that there will be somebody to awaken me, and so my consciousness may sleep tranquilly. But the unconscious has received communication of this decision, though the Me did not at all count on the unconscious. So the unconscious watches, is so wakeful, calculates time so exactly, that at the approach of the fixed hour it rouses us and recalls the Me to consciousness.

The following morning, at 5 minutes before 11 o'clock, Mr. Marillier and I were in the garden. The clock struck 11, and we saw Mrs. B. coming down-stairs from her chamber. She enters the parlor, looking for something. She touches several objects, without taking them in hand. She opens the wall closet, and shuts it again. Mr. Janet comes and bids her good morning; she makes reply, and then goes on with her indeterminate task, while walking up and down the parlor. Mr. Janet returns to us, and proposes to us to endorm the subject from a distance, thinking the experiment has failed. I object, saying that Mrs. B., not being quite in her normal state, might fall asleep of her own accord, and that we ought to wait and see what she would do. And all agreed that I was in the right; for, a few minutes later, at 11.30, Mrs. B. takes up an album, then another, opens it, sits on the sofa; and, now visibly quieted, begins to turn the photographs over. As she told us afterward, she was looking for the portrait of Mr. Gibert. "Why?" she was asked. "Because it gives me pleasure to see it." (That photograph had been taken out after it was found that once she was endormed spontaneously while looking at it.)

We go to the parlor and find Mrs. B. still engaged in thumbing the album, but she was in a state of *active somnambulism.* She did not this time say it was Mr. Gibert that endormed her: she did not even know she was endormed.

Naturally we profited by the occasion to make a few experiments. She again touched the thumbs of all present and recognized us easily. Mr. Janet asked her to continue her revelation about me. She

repeated her remarks of the other day: "He has a good deal—I don't know how to speak it—well, he has that which is needed to endorm." "A good deal of will-power?" asked Mr. Janet. "Yes, yes, a will-power—but I don't know how to call it—he thinks well. When one means to endorm me he must think well—else it torments me—some one wants to endorm me and thinks of something else; that annoys me. He has—I don't know—but I should not dare, for instance, to say nay to him—Oh, there! He could make me walk—make me walk into the sea."

"You want to leave us, then—Mr. Gibert and me?" "No; you are mine." "Then forget him!" "I will not." But at last she gives way, and we are able to proceed with the experiments.

I have forgotten to say that after the seance at Mr. Gibert's she was taken home in a carriage and awakened on her arrival, so that she retained no recollection of her night-wandering. While on the way home she said to the gentlemen that were with her that *I had something in my pocket which attracted* (the hypnoscope). Wishing to verify the fact I passed the magnet to Dr. Myers, who, according to the somnambule, had no influence over her. He put it in his pocket; while on the other side Mr. Frederic Myers, who was equally indifferent for Mrs. B., had another magnet.

Almost instantly Mrs. B. stretched forth her arms, attracted in two opposite directions. This attraction ceased in the state of active somnambulism, and then reappeared in one of the phases of lethargy that I was unable to define.

But little by little the order to forget me was blotted out of the subject's mind, and she showed again an attraction toward me, though now I had not the hypnoscope in my pocket. She rose twice and wanted to follow me. I went into the garden so as not to spoil the experiment, and Mr. Janet was obliged to repeat the order to forget. Finally, toward 2 o'clock, in the street I stopped the gentlemen to say to them this:

"You know I came to Havre mainly to verify the fact, till then unknown to me, of somnambulism at a distance. Now, the experiments we have made do not convince me. They are acceptable as regards action at a distance, but then they may also be explained by involuntary suggestions. In the first experiment Mrs. B. was not endormed till after she had seen that we were come. The second failed entirely; true, it was performed under exceptional difficulties, but at all events it proves nothing. The third seems conclusive; the subject came across town endormed. But for me there is a serious doubt. Mr. Gibert began the action at 5 minutes before 9 o'clock, whereas according to the cook Mrs. B. seemed to be already endormed 15 minutes before 9. I have ascertained that my watch keeps time with the clock in the parlor, and Mr. Gibert's is regulated according

to mine. Consequently we may suppose that Mrs. B. fell asleep of her own accord some minutes before Mr. Gibert began to act. Afterward she came, it is true, but I saw her at the garden gate, and it may be that she perceived one of us and that this circumstance suggested to her the thought of going out a few minutes after. In short, if we reject the testimony of the somnambule herself, certain doubts arise. To be absolutely convinced, I request Mr. Janet to endorm the subject *now*. The conditions are as perfect as can be. I noticed Mrs. B. from a distance and am perfectly certain that she is in her normal state, without any tendency to spontaneous somnambulism. No one is at this moment expecting an experiment. "Will you try it?"

It was cruel on my part, for we were all both tired and hungry; but I did not wish to go away without a clear conscience, and without being able to subscribe to the report that Mr. Marillier was to make to the Society of Physiological Psychology. Mr. Janet replied that he never had tried to act in the public street, that it would be impossible for him sufficiently to concentrate his thought, and that, on the whole, he preferred that the experiment should be made by Mr. Gibert. But at last he consented, provided he were permitted to act from his own house, *i. e.*, from a much greater distance, but where he would have the necessary quietude. I accepted the conditions, and it was agreed that we should first go to lunch together, to fix the exact time, and then try the experiment.

The matter was arranged as follows: I asked Mr. Marillier to go to the pavilion and watch Mrs. B. He did not act upon her, and so his presence could not have a disturbing effect. He was an *habitué* of the house, and therefore his presence could not awaken any suspicion. He did not know the precise time of the experiment, consequently he could not by his behavior influence the subject at the given moment. The precise time, fixed by lot after the departure of Mr. Marillier, was 4.30.

"We have still a good hour before us, but I'll not let you slip from me," said I to Mr. Janet, laughing. So we went together to take a cup of coffee, and then to have a stroll on the beach; at last, we went back to Mr. Janet's house, No. 3 Robert Alley. I kept up a lively conversation all the time with Mr. Janet, to keep him from thinking of Mrs. B., and so that there might be no excuses if by chance Mrs. B. should be endormed *before* the hour.

At 4.30 I withdrew to the little garden plot of his house, to give him entire freedom of action.

He sat in his armchair, his head between his hands, and concentrated his will so as to order Mrs. B., about half a mile away, to fall into somnambulism. This mental action lasted 18 minutes.

At 4.48 I enter Mr. Janet's study. He puts on his hat, and we go out to join the Messrs. Myers and proceed to the pavilion. Before

entering I asked Dr. Myers to go upstairs alone and call Mr. Marillier down. The latter said he had seen nothing. "All that I can certify," he declared, "is that since my arrival nobody entered the pavilion. As for Mrs. B., she probably is busy sewing in the parlor, but I did not enter the parlor for fear of exciting her suspicions." Before going in, I begged Mr. Janet to permit me to put the questions to Mrs. B. in case we should find her endormed.

Then we enter without ringing, as noiselessly as possible, and notice, through the door of the parlor, which was ajar, Mrs. B. engaged in sewing, but *in active somnambulism.* She did not hear us. *She answered only the questions put by Mr. Janet.*

"Well! You are tormenting me again! Do I look like a fool? It is you that are playing this trick upon me!"

"Perhaps it is Mr. Gibert."

"It is not Mr. Gibert at all, 'tis you."

"When did you fall asleep?"

"Just at half-past four."

"Did you look at the watch?"

"What need to look at the watch? I tell you it was half-past four."

I compared Mrs. B.'s watch with mine. It was 3′ 30″ slow; consequently, if she noted the time correctly, *the effect was produced from a distance in about 4 minutes after the commencement of the action.*

"Tell us what you have been doing since we left."

She then told us that first she went down to the kitchen for lunch, that she talked awhile with the cook, and then went up to the first floor to dress; that at last she took up her sewing and suddenly found herself paralysed, so that when the bell rang (on Mr. Myers entering) she was unable to rise.

She did not speak of Mr. Gibert this time as she had done always before.

Another point worthy of notice is that, as these gentlemen assured me, when Mr. Gibert endorms her from a distance, she is always *found in lethargy;* when Mr. Janet is the operator she falls into a less profound *somnambulic* state. The cook confirmed the somnambule's statements.

"Now, then, are you satisfied?" asked Mr. Janet, addressing me.

"Yes; this time the experiment is clear. One thing only I regret—that Mr. Marillier could see nothing. Thereupon we proceed to experiment.

From the beginning of our seances she had shown a certain repulsion toward Mr. Marillier, a purely physical repulsion against being touched by him; yet she would talk with him and show no sign of dislike. We ask the reason of this. She examines his thumb; then, letting go his hand, she says: "He makes me ill. Oh, not me—but—that does not concern you." Mr. Janet insists. Again she seizes

Mr. Marillier's thumb, touches his chest, then her own, with an expression of pain, and makes answer: "I do not wish—that does not concern you." All that can be got from her is that he is ill.

Mr. Marillier took me aside, and admitted that he had an affection of the heart, and but a few days before had suffered a good deal from it. The fact is mentioned in his study on Hallucinations.

With her habitual vivacity—habitual only when she is in the state of active somnambulism—Mrs. B. passes to other matters, amuses herself like a child, touches the hands of those present, always in the same way and with the eyes shut.

While she was holding a lively conversation with Mr. Janet, I made an experiment in mental action. It was without result. At that moment there was hyperæsthesia of the sense of smell, for a cigarette mouthpiece, held some twenty inches away, produced coughing and discomfort.

As she showed such marked impressionableness with regard to me, and as she believed I had left the house, I wished to find out whether she could recognize an object belonging to me. So I remove my cravat and pass it secretly to Mr. Janet by the hand of Mr. Marillier. Being at the moment occupied with other questions, Mr. Janet laid the cravat on the table. A few seconds afterward, the somnambule rose of her own accord, took the cravat, went straight to me, dropped the cravat into my lap, and went back to her place, acting throughout like an automaton. Was this an instance of thought-action on my part? At all events Mrs. B. did not recognize me; she merely carried out my thought, which had not been formulated as a mental order, and this she did mechanically, as though not knowing what she did. But the somnambule, despite her apparent inability to see, might have noticed my not having on the cravat. I therefore decided to make the same experiment over again with another object, and for this purpose I chose a bit of black ribbon that no one had seen me wear: this, too, I passed to Mr. Janet by the hand of a third person, not a word being spoken. Mr. Janet held the ribbon in his closed hand. Suddenly the somnambule opened his hand, took the ribbon, and as soon as she had touched it danced with joy like a child, saying: "He is there! He is there! He is not gone!" Then she asked for a piece of paper, and it was given to her. She wrapped the ribbon in this and held it out in the direction of me, to give it to me. I did not stir, and she grew impatient. Mr. Janet tried to take the little parcel from her, and her irritation increased. Then I took up a broad-brimmed hat, and with that concealed my hand and Mr. Janet's. The instant the parcel touched my hand, Mrs. B. smiled and tried to give it back to me; but when she found Mr. Janet's hand she withdrew the parcel, and showed signs of displeasure. After many experiments of this kind her agitation increased, and she had a real paroxysm of

hysteria, which Mr. Janet tried to quiet by applying his forehead to hers. (It seems that ovarian pressure has not this effect upon Mrs. B., who, I repeat, presents no symptom of hysteria in her normal state.)

To elucidate the question of her discernment of objects, I proposed to Mr. Janet to take three similar leaves of paper, touched by three different persons and marked by them. It was done, and an effort made to pass the papers to Mrs. B. But she objected strenuously, struggled, and would not touch them. She brushed them aside with her handkerchief, and was not quieted till she saw them on the floor. Then she threw the handkerchief on the sofa, and started when she chanced to touch it. When the three sheets of paper were by force laid in her lap, she struggled, threw herself back, and fell into lethargy. The experiment had therefore to be given up.

I was obliged to return to Paris, but one more experiment in endorming from a distance took place, under the direction of Mr. F. Myers. The details were communicated to me by Mr. Janet, as follows:

"On Saturday, after you left, nothing of real interest occurred, save an experiment in somnambulism produced from a distance, under precisely the same conditions as on the day before. The Messrs. Myers had me to lunch with them, and suddenly requested me to endorm Léonie at an hour they had agreed upon—a little before 3 o'clock. I thought upon it for a little less time than the previous day—about ten minutes—and we went forthwith to the pavilion, without waiting. Léonie was asleep over her work, as on the preceding day; she had been endormed just about 3:15. All that is known with precision is that she had gone upstairs to her work hardly a quarter of an hour before (at 2:45). It is further to be noted that no one had endormed her since the preceding day, and that I had not seen her that morning.

"Léonie said it was I that had endormed her. It seems that at that moment she had an hallucination—such, at least, is Mr. Myers's opinion. She kept saying that *she saw me endorm her.*

"During the sleep we did little more than repeat what you have seen already. . . . The sleep was disturbed by a storm which caused very violent paroxysms (*crises*) such as I had not seen before.

"The Messrs. Myers left Saturday evening. I endormed the subject once more Sunday morning, but I did it all alone in continuation of my researches.

"As soon as I shall see Léonie in her second state, which is for us the true one, I will convey to her your compliments.

"I am, etc.,

"P. JANET.

"Havre, May 4, 1886."

I left Havre with a profound emotion. I had at last witnessed the extraordinary phenomenon of action from a distance, which upsets all the opinions currently received. I summoned up my recollections, I questioned my notes a hundred times, to make sure of the reality of

what I had just witnessed. I examined the facts from the skeptic's point of view, if perchance they might be pure accidence and coincidence, then from the point of view of the magnetizer; finally, I looked at them in the light of the suggestional theory and of other intermediate theories, possible or fanciful; and I came to the conclusion that leaving out the first three experiments, which were inconclusive, the fourth stands and cannot be explained save by *a causal connection between an act of will and an effect produced at a distance.* But as I have already said, in questions of this kind one must himself make the experiments; one must himself have brought out—and that again and again—the phenomenon, with a subject and amid surroundings that he knows thoroughly, if he is to give a definitive judgment. Now, with regard to the action from a distance in this case, I was but a passive observer, and therefore I must have my reserves upon the matter. I have, however, verified mental suggestion from anear, but *I saw only one* experiment from a distance that to me seemed to meet all the requirements.

CHAPTER V.

NEW EXPERIMENTS.

A FEW days after my return to Paris I had occasion to make some further experiments upon two hysteric patients whom it was my duty to treat under like conditions.

Miss Z. was magnetized by me for hysteric paroxysms, complicated by physical exhaustion and marked anæmia. (Hypnoscopic exp.: sensation of cold and slight analgesia.) The first seance gave no positive result, except that my hands were chilled in quite an extraordinary degree. The patient, having passed through a torpor hardly perceptible to her, felt a little better, but did not admit that the magnetism had had any effect. The second seance produced magnetic sleep, and then a rather protracted paroxysm, but the transition from waking to sleep and from sleep to the normal state took place so imperceptibly, that she would not believe in the sleep, and was almost quite unconscious of having had the paroxysm.

At the third seance, she told me that she did not at all believe in the sleep produced, and said that I should never succeed in endorming her; that if she remained for a time motionless that was because such was her good pleasure, but that should she only try to make a little resistance, I should have no influence. I advised her not to open a discussion that led to nothing, and said that if she persisted in her resistance I should prefer doing nothing, lest I should produce

useless excitation. But my efforts to persuade were in vain; on the contrary, Miss Z. was set in her purpose to convince me, and positively asked me to endorm her against her will. As that experiment could not, in the present case, cause serious mischief, I at last consented.

After a few minutes she was endormed by fixing the gaze, but straightway passed into somnambulic delirium, constantly repeating: "No! I won't! You shall do nothing with me!" Little by little the delirium became a spoken dream lasting more than an hour. The patient remained seated and quiet, heard only me, but was not quite obedient. I told her to go to bed, the hour being late. She refused, saying she was very well as it was, and that she wanted to be left undisturbed.

I might have awakened her, but from what I had seen I was almost sure that the awaking would bring about an hysterepileptic paroxysm in the normal state, contrarily to the therapeutic principle of magnetism. (My treatment of hysterepilepsy by magnetism consists in this: I transfer, so to speak, the paroxysms to the magnetic sleep, and thus suppress them by degrees in the normal state. The cure is complete when a paroxysm can no longer be produced even in the somnambulic state.)

At this moment a young lady companion entered the parlor quite noiselessly and looked with astonishment at Miss Z. "Do not look at me," said the latter. "You make me ill." (The patient's eyes were shut, and she was some twenty-five feet distant from the visitor.) Miss Marie, the caller, withdrew frightened. But the patient still kept crying out to her: "*Do not think on me!* You make me ill."

These words, which might have been dictated by a presumption and not by a real psychic action, recalled to my mind Mr. Gibert's experiment. Wishing by hook or by crook to get the patient to bed so that I might leave, I tried unconscious psychic inoculation. I applied my forehead to hers, saying mentally: "In five minutes you will want to go to bed." The patient continued to rave, and seemed in no wise influenced by my action. Five minutes passed and she said nothing to me. Then I advised her, for the tenth time at least, to go to bed. "*As you wish,*" she answered. She went to bed and perforce believed in magnetism now, for the next day she was unable to account for her being there.

Mr. Gibert believed strongly in the efficacy of mental action by contact of foreheads. He has told me that often he has in this way arrested violent hysteric paroxysms. I wished to test the matter, and an opportunity soon presented itself.

Miss S., to all appearance, sound, strong, not at all anæmic, was subject to attacks of the major hysteria of great violence, but very infrequent. One might even say that hers was *latent hysteria*, for it

manifested itself only under the influence of moral causes at intervals of several months, or even of several years. Still, it was the greater hysteria, a very serious case, presenting all the chief phases so well analyzed by Mr. Charcot, including the period of delirium at the end of the attack. This always lasted several hours, nay, a whole night. Miss S. was very sensitive to hypnotism, and that explains the intensity of the attacks. (Hypnoscopic exp. : insensibility and torpor soon extending to the whole nervous system, producing an hypotaxic state very much like sleep.)

Once I made with her some experiments in mental suggestion with playing-cards. The result was rather remarkable. She never divined quite aright, but she *always* had a perception correct in part, and always in accord with the visual, but not the auditive characters. For example : I thought of the deuce of spades, she divined tray of spades ; I thought of the queen of hearts, she divined jack of hearts ; ten of clubs, she said nine of spades ; and so on. In divining, she shut her eyes, bowed her head, and remained absorbed in a visibly monoideic state that struggled with the ordinary impressions. After a quarter of an hour of this exercise her countenance was changed, and gave tokens of great fatigue. I interrupted the experiments, and to bring her back to herself made a few awakening passes. I was wrong ; I ought rather to have endormed her completely, and allowed her to take repose in that state. For a moment she was freed from her enervation, and seemed entirely well. But the shock had been produced, and the partial disturbance of the normal equilibrium brought about an attack.

We were at table when I was notified that Miss S., who had gone to her chamber, was writhing in convulsions. I hastened thither and found her on the floor in a fearful paroxysm. She was rolling on the floor so violently that I had all that I could do to hold her by the arms ; but restrain her I must, for she was dead set upon dashing her head against any hard object whatever, or throwing herself out of the window. Then I tried Mr. Gibert's plan ; but it was without result, whereas ovarian pressure stilled the paroxysm a little, at least for a few moments. In such cases it is difficult to endorm the subject. The struggle lasted three hours. After the first hour she was already a little influenced, and about every ten minutes she fell into a somnambulic dream, with rapport ; but by reason of the quite surprising force of her convulsed muscles, and of the necessity of keeping her in restraint unaided (she could not brook the touch of another person), I found myself exhausted, and every time I brought about a beginning of sleep, it was broken by frightful convulsions. At last, after a dozen attempts at suicide, a quiet delirium appeared ; she became voluble in speech, passed again in imagination through divers episodes of her life, but remained calm by my side, answered my questions, and

was beginning to obey me. I induced her to rest on a bed, and there little by little lucid somnambulism got the better of the attack. The rapport was well defined; she heard only me, and that only *when I wished her to hear*, so that we talked about her all the time, aloud, without her knowing it. The slighest touch by a stranger, even through the bed clothes, even when the sense of touch could give her no information, produced irritation and threatened her with a new attack. While speaking in somnambulism she always addressed me in the familiar form of speech—*thee, thou;*[1] consequently I did the same. "Go and rest now," she said: "I shall sleep quietly till 10 o'clock tomorrow morning. At that hour you will come and awaken me." I went home and slept like a marmot. On the morrow at 9:30 I entered her chamber.

"I heard you coming along the street," she said, "but do not awaken me yet. It is not yet 10 o'clock."

"Did you sleep well?"

"Yes; *because you did.*"

I found that the head was still a little hot, and offered to endorm her a little more deeply, to calm her. She assented. I made several passes without contact, and then went to the parlor and waited, reading a newspaper at a window. Suddenly I heard a noise like that of a falling body. The noise came from the street, but I fancied it came from her chamber, and for a moment I feared she had been seized by a new paroxysm. But that alarm shot through my mind like a flash, and lasted hardly one second; immediately the reflection came to me that there was, at that moment, nothing to fear, and I did not even stir from my place nor change my position, but kept on reading.

After a quarter of an hour I went to the patient's room, between which and the parlor was another large room looking into the courtyard, not upon the street.

I touched the patient's head and found it hotter than before. "Why?" "Because you are alarmed about something," was her answer. "Not at all," I replied, forgetting at first the trifling occurrence in the parlor; "why should I be alarmed?" "I don't know, but you are alarmed, and that has given me a congestion."

At this moment she was in *an inert polyideic* state (she exercised thought, but made no spontaneous movement).

I calmed her head by laying my hand upon it, and then tried mentally to suggest to her some movements, but without success. A little after I spoke quite near to her, addressing her, but intending not to be heard. She answered, nevertheless. I now formulated the order that I was not to be heard, and then recommenced the same

[1] The English language has lost the faculty of exhibiting this distinction.—*Translator.*

experiment in other words, and without any possible verbal suggestion. *She did not hear.*

"You will awaken me soon and I shall not have any more paroxysms."

"No more?"

"No more. I shall recollect nothing, and you must not tell me what passed during the night. Furthermore, you will give me your word that you will never try to act upon me from a distance."

"And do you think that would be possible for me—to act from a distance?"

"Yes; but you must not do it, for that would make me ill; I should be worried all the time."

"And if I promise you that, you will be no more made nervous by my presence?"

"No!"

"How do you recognize the touch of a third person?"

"Because it is disagreeable—strange—different—unbearable."

Miss S. was serious-minded in the sleep. She was always grave and laconic in somnambulism, and never laughed, a fact which gave a peculiar air to that state. She said that it would be preferable to endorm her entirely, instead of wanting to awaken her quickly. "But that makes no difference," she added; "I shall not have a further attack, *because you have let me have a long sleep.*" In reality she slept fourteen hours consecutively.

"Awaken me now, *but quite gently.*" (A request often made to me by somnambules in like cases.) So I awakened her very slowly, taking some twelve minutes to do it, by means of transverse passes without contact. At length she smiled, opened her eyes, and looked around surprised. She asked what meant my presence at her bedside, and recollected nothing.

During the following days there was only general fatigue and a little pain in the spleen, and that disappeared by degrees. In the evening she had headache. I removed this pain by imposition of hands, but on leaving I had a slight headache myself. I went to see another patient, *who never had had headache*—at least so she assured me many times. This patient I put to sleep (it was very difficult to endorm her, but the sleep was very deep). My headache disappeared. I awoke the patient after half an hour.

"I am doing very well, don't you think so?" she said (she is ataxic). "But this is odd, my head pains me a little; something that has never occurred before to me." I removed her headache, which disappeared for good.

I smile as I write this narrative, so strange and incredible does it seem to me. But to proceed; I have not yet exhausted my casket of surprises:

I saw Miss S. again that evening. She has headache again, and my hands are exhausted, my skin burning. I feel a disagreeable moisture (*moiteur*). I dip my hands in cold water, but all I can do is to allay her headache for a few moments. So with regard to the pain in the spleen. A cold compress cools her head, but does not banish the pain.

The following day I felt refreshed, and easily banished, in the case of another patient, a very intense headache attending an attack of fever and lasting three days. After this I found a fourth patient suffering from a slight headache. I may remark that I am unable to fix the precise moment at which my hands regained their force. I was reading *a book that pleased me much*, and suddenly I felt the disagreeable dryness (*sécheresse*) of my hands disappear, and regained my wonted feeling of a certain agreeable freshness.

I will cite one more complementary observation, since all this helps to throw light upon our problem.

When I find my eyes fatigued from reading I go to the theatre, and there, looking at things from a distance serves to give them rest. But sometimes, in order to refresh the eyes, I press the palms of my hands upon the lids.

Now, when the hands are exhausted I experience no relief, but if only some scene in the play, or a well-spoken phrase produces in me an agreeable emotion, my hands at once regain their therapeutic quality, and then if I apply them to the eyelids, the fatigue of the eyes disappears.

I reached the house of Miss S. "What were you doing last night at 11 o'clock?" she asked, abruptly. Inferring some somnambulic eccentricity, I said to her: "Ah, no! You shall first tell me what you know, and I will tell you whether it is correct."

"So be it. You were writing the whole evening, and it was not letters, for I saw big sheets of paper. You did not read a book, but you wrote all the time, and then at 11 o'clock went to bed, but were unable to sleep, and so got up again and walked up and down your room, smoking a cigarette."

Here a person who was with Miss S. the preceding night informed me that after going to bed she did nothing but repeat continually: "Oh, my God! When will he go to sleep? He prevents me from sleeping." I said nothing, and Miss S. continued her story:

"Then, at last, toward 1 o'clock, you fell asleep, and woke just at 7 in the morning. Is that so?"

It was all precisely so, barring a constant slowing of the time. That is to say, she "saw" me still writing at 11 o'clock, whereas I quit writing about 10.45. But it is precisely so that I did not read any book, that the whole evening I wrote on large sheets of paper, that, unable to sleep (my mind being preoccupied), I got up again

(quite exceptional this, for I never have had that habit), and so forth. The hour of rising was also stated correctly, within a few minutes, though about that time I was accustomed not to get up till 8 o'clock.

I add that Miss S. had no knowledge either of my domicile or of my habits, and that I lived about half a mile away.

It was difficult to accept mere chance as an explanation, but then what did this mean? Here is all that I can say:

Until that evening I had not had time to take notes upon Miss S.'s case. Without any thought of acting upon her, having indeed promised that I would not, I began to recall to mind exactly all that had occurred the other day, and it is my custom to make my notes very circumstantial. Consequently *I thought of Miss S. the whole evening.* As the matter involved certain rather interesting details from the theoretic standpoint, this mental occupation kept me from sleeping and all the time my thoughts dwelt upon questions in which she played the chief part.

As for Miss S., she retired to bed early and in a half-sleep believed she saw all that took place with me, but she declared that my mental occupation prevented her from sleeping and that she was angry at me, feeling a sense of strange dependence which she could not rid herself of. At last on awaking at 7 o'clock she felt as though I also had awaked.

The day following, also, she had a similar sensation, less clear, however, and then this rapport disappeared.

The case then probably was one of "veridical hallucination."

I know other facts of this kind, but I do not wish to raise this question here. It seems to me as yet too difficult and premature. I give this narrative only as a simple piece of evidence, and I shall be content in the sequel with analyzing the direct experiments, which seem to me more palpable.

The reader will find in the work compiled by Messrs. E. Gurney, Frederic Myers and F. Podmore, under the auspices of the London Society for Psychical Research, several hundred similar cases, well attested and collected for many years. Its title is "Phantasms of the Living" (2 vols. London, 1886).

I will add only that Mrs. M., too, believed she saw me on the occasion of my address to the Society of Physiological Psychology, January 25, 1886, in which I spoke of *experiments made upon her;* but she was informed of it beforehand. Still there were some details of which she was ignorant but which she saw in her dream, to wit, that while I spoke "I was concealed as high as the chest by a green table."

Was that thought-transference? Perhaps it was.

PART II.

FACTS OBSERVED BY OTHERS. EVOLUTION OF MENTAL SUGGESTION. PHYSICAL ANALOGIES.

CHAPTER I.

ORGANIC SYMPATHISM.

IS the surface of one body capable of transmitting, whether with or without contact, certain of its organic states to another body? Such is the question. We will begin with an examination of the physical states, passing thence to isolated sensations, and finally to thoughts. We shall therefore have to study:

A. Physical nervous transmission of diseases.
B. Transmission of emotive states.
C. Transmission of sensations.
D. Transmission of ideas.
E. Transmission of will.

Then we will study separately.

A. Suspended mental suggestion.[1]
B. Mental suggestion from a distance.

The history of magnetism contains many facts, more or less ill-observed, more or less ill-attested, appertaining to the foregoing categories, but they contain also a certain number of positive observations that ought to count.

Hitherto I have restricted myself to telling of what I have myself seen, judging that in this sort of phenomena one must himself be observer, actor and critic, in order to accept others' testimony. Otherwise one would have simply to accept *all* the alleged facts of magnetism, for all, or nearly all of them, are vouched for by respectable witnesses. Besides, no man can boast of such authority in science,

[1] That is, suggestion to be executed at a future time. I know not how to translate otherwise the convenient French phrase *suggestion mentale à échéance*.— *Translator.*

that he can introduce into the scientific domain an entirely new fact, theoretically isolated from all other facts, in short, unexplainable. Hence the precaution I imposed upon myself and on the reader had no aim, no significance, other than to make the latter a witness of the course of my studies, of the progressive development of my convictions, and hence of my methods. Plainly I do not hold that my testimony is worth more than that of other physiologists. I only say—excuse my egoism, if egoism it be—that it was worth more for me. And since one must be answerable for a book as for an act that endures, I do wish to have a clear conscience. That will, perhaps, not prevent the skeptics of scientific officialdom from taxing me with credulousness, and I shall be the first to understand and to make allowance for their skepticism ; but it certainly will save me from self-reproach in the future. That, I take it, is all that a writer can do. Unfortunately, authors have not always taken this precaution.

You wish to study in the history of magnetism the phenomenon of mental suggestion and you are looking for testimony of real weight. You open a book on hypnotism and in it find banter about mental suggestion ; those worthies never have studied it, but they assure you of the exactness of their negative judgments, based on the witness of other men of science, who in turn have not studied it either. At last you find a grave author who believes in mental suggestion.

Take Dr. P. Despine the younger, author of a big treatise in three volumes on "Natural Psychology"—a work very little known in France, but abroad justly prized. Mr. Despine has also published during the last few years a book on somnambulism. He believes in mental suggestion, even proposes a theory of it ; but as for facts, he has himself seen none. He refers to other respectable authors and especially to Dr. A. Bertrand, an excellent observer who published (1823 and 1826) two volumes on somnambulism and magnetism, wherein he treats at considerable length the phenomenon in question, but declares that he has no positive evidence drawn from his personal experience. He merely says that the number of testimonies that presented themselves in favor of the existence of this phenomenon in the different works wherein he sought information about ecstasy, compelled him to believe in spite of himself and obliged him to give more attention to the testimonies of the believers in animal magnetism. And he refers chiefly to authors of past times, to Father Surin, "a man of genuine piety, to whom the majority of his enemies did not refuse to do justice, but credulous *beyond all possible imagination.*" He refers to Poncet, author of religious books, an equally estimable personage, and to Madame Guyon, the best possible witness, for she "read the thoughts of Father Lacombe, her confessor, as he read hers."

I am only half in play. Bertrand, too, was but half serious when he said that he had not met with facts of mental suggestion in his

practice. He met with a few, and I will quote them in due time and place, as I shall also cite the facts observed by Father Surin and by Mr. Poncet, for they possess a certain value because of special circumstances.

But had I no other evidence than the testimony of Father Surin, Mr. Poncet, and Mme. Guyon, think you I would have published a book on mental suggestion, or so much as mentioned the existence of that phenomenon? Not I! Neither assuredly would I have denied it, for I never deny what I am ignorant about; but from that to a scientific affirmation of so strange a fact is a long way.

That is why I took care not to begin, as is the wont, with the history of the subject, and therefore with ancient testimonies; but now things are different. I have seen, myself clearly seen, and therefore I can have faith in the testimony of those who have seen the same thing, and it would not be fair for me to hide from the reader observations not my own. On the contrary, I wish to quote them all; that is to say, all that have the appearance of truthfulness, that have been well proved, and that are clearly analogous to those observed by myself. This latter proviso will be pardoned me, for without it I should be obliged to quote also things incredible, at least just now, and it is always prudent to advance slowly over unfamiliar ground in the dark.

I will array the subjects according to the classification given above, adding my comments, so as to present a full inventory of the known facts of mental suggestion, upon which will be based the theory, or rather the beginnings of the theory of the future. We will begin with a phenomenon seemingly foreign to our inquiry, often found in the writings of magnetizers, to wit: the *appreciation of diseases by somnambules*, and the alleged power of *seeing the diseased organs*. Let not the reader be surprised at finding the matter considered here. It is essential, as will presently appear.

1. "I observed (writes Dr. Bertrand) a somnambule who, I was told, possessed the faculty of discerning diseases. . . . But not content with what they told me about her, I wished to test her with regard to a patient whose state I knew beforehand. So I brought her into rapport with a young lady whose chief malady was an attack of asthma, which afflicted her very often. When the patient came, the somnambule was already endormed, and I was sure that she could not know the person I brought to her. Nevertheless, after contact for a few minutes, she seemed to respire with difficulty, and soon *she experienced* all the symptoms that attend a violent fit of asthma; her voice was suppressed, and with much effort she told us that the patient was subject to *the kind* of oppression that her coming had imparted to herself. Nor did she limit herself to that, but added to what she had just said details of several local complaints and pains to which the patient was subject, and which she recognized with the greatest precision *by means of the sufferings she herself experienced in*

the corresponding parts of her body; but what in the most unmistakable way showed the somnambule's faculty was the discovery she made of an herpetic affection with which the patient was troubled in the genital parts. None of us had knowledge of this, and the patient alone could tell us how correctly the somnambule had hit it off in this respect."[1]

Bertrand adds to this observation the following remarks:

"In general we must, in consultations with somnambules, distinguish what they say they *experience through contact* with the patients from what they *fancy they see* within their bodies. What they say they feel is worthy of credit, while what they infer from what they believe they see never presents aught but baseless conjectures, often quite absurd."

2. "I showed," says the same author, "to another somnambule a female child of 4 years, one of whose arms was crippled in consequence of a fall which had produced a deposit in the shoulder-joint; further, a vice of constitution made her gait awkward, and she swayed from one leg to the other. The child was brought to the somnambule, and, during the whole time of the consultation, was held in the lap of the person who carried her. Thus, nothing could have taught the somnambule in advance what she should say. Yet, this is what happened. When the child was presented to her, the somnambule raised, with difficulty, her own flexed arm, seemed to make vain efforts to raise it to her head, and exclaimed: 'Oh, the poor child, she is crippled!' On being asked what had caused the trouble she had just found out, she answered, 'A fall' (and that was the fact). After this first remark she said nothing for a little while, and then continued: 'Oh, my God! how weak she is in the loins! She must have much trouble in walking.'"[2]

3. "I was with the somnambule, whom I was magnetizing as she lay on her bed asleep, when I saw coming in a friend of mine accompanied by a poor fellow wounded a little before in a duel, a ball having entered the skull. I put the somnambule in rapport with the wounded man, and limited myself to asking her to say what ailed him. She seemed for a moment to be trying to find out, and then, addressing herself, said: 'No, no! It is impossible. If a man had a ball in his head he would be dead.' 'Well,' said I, 'what then do you see?' Said she: '*He* tells me that the gentleman has a ball in his head.'" (*He* was, according to the somnambule, a distinct being, separate from herself, and whose voice came from the pit of the stomach; a sort of guardian angel, *scilicet*, the Unconscious. It is probable that this notion of a revealer was suggested to her by some spiritist magnetizer.) "I assured her (continues Bertrand) that what she had said was true, and asked her if she could see where the ball had entered and what direction it had taken. The somnambule reflected a moment, then opened her mouth, and with her finger indicated that the ball had entered through the mouth and penetrated to the posterior part of the neck. This, too, was correct. Finally, she carried exactitude so far as to point out some of the teeth that were lacking in the mouth, and which the bullet had broken. The somnambule had not opened her eyes since the moment when the wounded man entered the

[1] Bertrand, "Traité du Somnambulisme," etc., p. 229. Paris, 1823.

[2] *Id.*, p. 232.

chamber. There was no lesion of the external integuments of the mouth."[1]

In his second work[2] Dr. Bertrand expresses himself in these terms:

"We find in the works of magnetizers very many instances of this phenomenon, and I myself have had occasion to verify it several times in such a way as to leave no doubt. There is no one, I believe, who has made any little observation of a few somnambules, but that has often seen them by simple contact feel the *pains* of the patients with whom they have been put in rapport." (Bertrand employs this term, consecrated by its use among magnetizers, but he attaches to it no other meaning but that of contact; he does not accept the "magnetic fluid" hypothesis.) "The impression thus received is commonly but momentary, and very rarely do they on awaking retain the symptoms communicated to them during the sleep. A few exceptions to the rule may be met, however, and in order that the somnambule retain the disease for a considerable time, he needs but to be convinced, from what he experiences, that he has really caught it from the patient. . . . That, apparently, is what happened to some of the 'Convulsionaries' of Saint-Médard, who thought that God accepted them as victims and permitted them to take the diseases of those who came to consult them. 'It often happened to the Convulsionaries,' says Carré de Montgéron, '*to take diseases without knowing whether the persons were ill* and in ignorance of the nature of their ailments. They were informed of these things by *the sense of pain they felt in the same parts.* It appears also that then the sick, witnesses of the singular phenomenon before their eyes, *believed themselves to be freed from their ailments* as soon as those ailments had passed into the bodies of the Convulsionaries. Thus we see one Chevalier Deydé relieved of his fits of dizziness after Sister Jane had taken them.' Among the *possessed*, when the exorcization was protracted for a sufficient time to accustom them to the terrible situation in which they were, many likewise believed themselves supernaturally informed as to the diseases of the persons present, and thus they presented the strongest resemblance to the Saint-Médard Convulsionaries and to somnambules. . . . .

4. "The documents concerning the trial of a (hysterepileptic) 'possessed' person named Mary Bucaille, in 1699, contain, with other matter, proofs of the phenomenon of the transmission of diseases. These proofs are the more worthy of attention because the prosecution confirms them as well as the defense, with the difference that according to the latter the phenomenon proceeds from a gift of miracle-working accorded by God himself, while according to the former it is of the devil's doing. Now, this Mary Bucaille had suffered in her person the ailment of Ann Séville, and evidently she must be a witch and a sorceress, 'it being the way of sorcerers to cure people by taking upon themselves their diseases.' The counsel for defense regards this assertion as proof of great ignorance on the judge's part, for 'he has always heard it said that a sorcerer, in curing a sick person, oftentimes casts the *maleficium* upon another person; but no one ever has heard it said that the sorcerer *takes the ailment upon himself;* and thus, in the cures that God has wrought by

[1] Bertrand, *ib.*

[2] "Du Magnétisme Animal en France," etc., pp. 428–430. Paris, 1826.

the said Bucaille, if she has in truth taken upon herself the ailments of the sick, as is proved as well with regard to the present case as with regard to the aged parish priest of Golleville and other persons that have been mentioned, then this way of curing others is something greater and nobler than other miraculous cures, which are performed by a single word,'" *et cetera.*[1]

What the possessed and the Convulsionaries did of themselves, under the influence of disease, somnambules did under the influence of magnetizers. The first fact of this kind known, being one of the experiments of the Marquis de Puységur, is given by Clocquet, in a letter dated Soissons, July 13, 1784, hence prior to the publication of Puységur's own narrative, which did not take place till toward the close of the same year.[2] Clocquet went as an impartial curiosity-seeker to witness the Busancy miracles.

"Attracted like others to this spectacle [he says], I took thither merely the dispositions of a quiet and impartial observer; fully resolved to be on my guard against the illusions of novelty; fully resolved to make good use of eyes and ears."

But here is what he tells:

5. "Mr. de Puységur chose from among his patients several subjects whom, by touching them with his hands and holding toward them his wand (an iron rod about fifteen inches in length), he caused to fall into a regular crisis. The complement of this state is *an apparent sleep*, during which the physical faculties seem suspended, but to the profit of the intellectual faculties. The eyes are shut, the sense of hearing is null, and awakes only at the master's call." (This is the phenomenon of isolation peculiar to the *magnetic sleep*, as distinguished from the *hypnotic state*, produced by an inanimate object.) "One must be careful not to touch the patient in the crises, *nor even the chair he sits in.*" (I have often, since 1867, observed and verified that fact.) "Were one to do so it would cause great suffering; convulsions that only the master can allay. These patients in the crisis,[3] who are called *médecins* (doctors), have a supernatural power whereby, on touching a sick person presented to them, or on *laying the hand upon him, even outside the clothes*, they know what internal organ is affected, the part of the body that is ailing. They name it and give pretty correct advice as to the proper remedies. I had myself touched by one of the *médecins*—a woman of about fifty years. I certainly had not told anybody the nature of my complaint. After giving some time to my head in particular, she said that I often had pain therein, and that I habitually had a loud buzzing in the ears, which

[1] "Du Magnétisme Animal en France," etc., p. 430.

[2] To the Marquis de Puységur is usually attributed the discovery of artificial (*provoqué*) somnambulism and of the faculty of which we are speaking; but one has but to read Mesmer's second "Mémoire" to be convinced that the founder of mesmerism knew of both phenomena. It is certain that he kept secret a portion of his experience.

[3] The word *crisis* has here the same meaning that Mesmer gave it. In general it signifies *any nervous state different from the normal* brought about by the processes of magnetization or by the patient's imagination.

is quite true. A young man who witnessed this experiment with incredulity, submitted to it himself afterward, and was told that he had trouble with his stomach, that he had engorgements in the lower abdomen—this since the occurrence of a fit of sickness a few years before. This, he confessed, was in accordance with the facts. Not contented with this divination, he forthwith went and had himself touched by another 'doctor,' twenty paces away from the first, and got the same answer. I never saw a man so dumbfounded as this one, who surely had come to contradict, to jeer, and not to be convinced."[1]

In a book published the same year (1784) under the title "Réflexions Impartiales sur le Magnétisme Animal,"[2] we find the following remarks upon the report of the royal commission :

6. "While the commission were making so many experiments, I wish they had extended their observations to one of those *somnambules*, made such by magnetic action, and subjected him to the following tests. After blindfolding him with the bandage employed in the other experiments, I should have liked to see them bring before him different persons whose ailments they knew, and ask him to tell what the ailments were. If this new style of doctor should discover the seat of diseases merely by contact, I rather think it would not be possible for the members of the commission to say that touching the patients produced the ailment, and that imagination or touch had anything to do with it. This experiment is decisive. *It has been made before my own eyes in Mr. Mesmer's practice ; and since then I have seen it repeated at Lyons many times with success*, every precaution being taken to prevent trickery. The different somnambules that served in the experiments were young women of the people. To them were brought sick persons unknown to them : they pointed out with the greatest exactitude the ailments with which these were affected. I have seen them *feel sharply the ailments* of those whom they magnetized, and make those ailments known by pointing toward the region of the disease in their own body."

In August, 1825, Dr. Foissac addressed to the Paris Academy of Medicine a letter in which he announced in the following words the phenomenon of the transmission of aches :

"By placing the hand successively on the head, the chest, and the abdomen of an unknown patient, the somnambules discover instantly his *complaints* and *aches*, and the various *symptoms* these occasion."

Here follows an account of the *instinct for remedies*, which does not concern us. Foissac exaggerates this, as he exaggerates also the diagnostic instinct, presenting as a general rule what is only a phenomenon more or less rare. The few somnambules he chanced to meet inspired him with unlimited confidence, which soon disappeared as his experience grew a little larger. He continues :

"There is no disease, acute or chronic, simple or complicated—and I except none of those which have their seat in either of the three

[1] Quoted by Bertrand, *id.*, p. 222.

[2] Page 228.

splanchnic cavities—that the somnambules cannot discover and treat suitably ; *for the case is not the same with those which are seated in the members and at the surface of the body, if they produce no general reaction, or do not disturb any essential function.*"

This restriction is important, especially when made by a competent enthusiast. Foissac, then, sees that if communication of symptoms is to take place they must proceed from a rather pronounced and rather profound disturbance of the vital equilibrium. And if somnambules do not judge equally well of local disorders "in the members and on the surface of the body," the reason is that the faculty here in question does not consist in *seeing*, or as Foissac himself puts it, in "*reading the inmost structure of the most hidden organs*," but that it is rather the faculty of *feeling* the disordered state of a disequilibrated nervous system. This disorder must be pretty considerable in order to react upon the somnambule as an electric charge in a conductor body acts on a distant galvanometer.

Full of confidence, Foissac proposed to the Academy a scientific investigation :

"Take (said he) in this city—at the Central Bureau or in one of the hospitals—three or five of the most pronounced or most characteristic cases of disease, and let these form the subject of the first test ; for the second test you shall select the most obscure or the most complicated cases. The somnambules, I pledge my word for it, will give all the more convincing proof of their sagacity as the difficulties shall be greater. These experiments shall be repeated as often as may be agreed upon in order to convince you fully. A commission named by you shall observe all the details, and will render to you their report thereupon, and to that I will add my report. If you are not satisfied with their operations, you shall select others. Should I have any complaint to make against any of them, I, too, should have the right to name others. The truth could not fail to be arrived at by so rigorous an investigation."

True, but it is a rare occurrence for an academy to take an interest in a new truth. On the contrary, it is matter of frequent observation that academies care more for professional dignity than for the advance of science. This is a psychological phenomenon no less interesting than several others, but we mention it only in passing. The fact is that Dr. Foissac's letter was not even read to the academy, and that Mr. Adelon, the Secretary, judged it sufficient to acquaint the academicians with its purport. After a long and noisy discussion, the academy named a commission whose duty was to report "whether *it is fitting*, yea or nay, that the academy take up the question of animal magnetism."

Adelon, Pariset, Marc, Husson, and Burdin were on the commission. Husson was named Secretary.

After four months, December 13, 1825, the report was read to the

academy. It was a thunderbolt. Taking the works of Bertrand, Deleuze, and Georget for a basis, the commission decided in favor of the examination. Still, not till after several indecisive sessions was a commission of eleven members, nearly all unbelievers, authorized to begin the investigation. That was on February 14, 1826. The question of *fittingness* was decided by a vote of 35 yeas against 25 nays.

The commission experimented for five years, and its report was presented to the academy by the same Dr. Husson, June 28, 1831. It was entirely in favor of magnetism, and even confirmed the idea of action from a distance. As for the question which specially interests us, here is what the report says :

"There is not one of you, gentlemen, who in all that has been said to him about magnetism has not heard tell of the faculty possessed by certain somnambules, not only of defining the kind of diseases with which they are affected, the duration and the issue of those diseases, but also the kind, duration and issue of the ailments of persons with whom they are brought into rapport. The following three observations have seemed to us so important that we have believed it our duty to make them known to you in their entirety, as presenting very remarkable examples of this intuition and this foresight : . . .

7. "The commission found (says the report) among its members one who agreed to offer himself for the purpose of having his ailment pointed out by the somnambule (Miss Céline Sauvage). This was Mr. Marc. Miss Céline was asked to examine attentively the state of health of our colleague. She *applied her hands to the forehead and the region of the heart*, and in three minutes said that the blood was tending to the head ; that at that moment Mr. Marc had trouble with the left side of that cavity ; that he often had a feeling of oppression, particularly after eating; that he must often have a light cough ; that the interior part of the chest must be gorged with blood ; that something interfered with the passage of the food ; that this part—designating the region of the xiphoid appendage—was contracted. . . . . We were longing to learn from Mr. Marc whether he felt all that the somnambule had declared. He told us that in fact he had a sense of oppression when he walked after meals ; that often, as she said, he had a cough ; and that before the experiment he had an ache in the left side of the head, but that he was unconscious of any interference with the passage of his food. . . . .

8. "There was another woman, 23 to 25 years of age, suffering for the last two years with ascitic dropsy accompanied by numerous obstructions, some the size of a hen's egg, others the size of the fist, some as big as a babe's head, the large ones having their seat in the left side of the abdomen. The exterior of the abdomen was uneven and lumpy, and these inequalities corresponded to the obstructions, the seat of which was in the abdominal cavity. Mr. Dupuytren had already ten or twelve times performed puncture on the patient, and had always drawn off a large quantity of albumen, clear, limpid, odorless, and without any admixture. Relief followed. The writer was present thrice at this operation, and it was easy for Mr. Dupuytren

and him to ascertain the volume and hardness of these tumors and consequently to see their own powerlessness to cure the patient. They prescribed, nevertheless, different remedies, and they attached some importance to this, that Miss . . . (the patient) should use the milk of a goat rubbed with mercury. February 21, 1827, the writer went in search of Mr. Foissac and Miss Céline, and took them to a house in the Faubourg du Roule, without telling them the name, the dwelling place, or the nature of the malady of the person whom he wished to submit to the somnambule for examination. The patient did not make her appearance in the chamber where the experiment took place, until Mr. Foissac had endormed Miss Céline, and then, after *taking one of the patient's hands* in her own, Miss Céline examined her for ten minutes, not as a physician would, by pressing on the abdomen, percussing it, scrutinizing it in every way, but *merely applying the hand again and again to the belly, chest, back, and head.* Asked what she had observed in Miss . . . , she replied that the whole abdomen was diseased, that there was a schirrus and a great quantity of water in the region of the spleen, that the intestines were much distended, that there were pouches containing worms; that there were tumors as big as an egg in which was contained pus-like matter, and that these tumors must be painful; that at the bottom of the stomach was an engorged gland the bigness of her three fingers, that this gland was in the interior of the stomach and must needs impair the digestion; that the disease was of long standing; and finally that Miss . . . must have headaches. She advised the use of an infusion of borage and of nitrated triticum caninum, 5 ounces of the juice of pellitory, taken every morning, and a very little mercury taken in milk. She added that *the milk of a goat* that had been rubbed with mercurial ointment half an hour before milking would be better.[1] The nourishment should consist of white meats, gruel with milk, but no lemons. She allowed very little wine, a little rum, *à la fleur d'oranger*, or peppermint *liqueur*. This treatment was not observed, and had it been it would not have saved the patient. She died a year afterward. As the body was not opened it was not possible to verify what the somnambule said. . . . . .

9. "In a case of some delicacy wherein very skillful physicians had prescribed mercurial treatment for an engorgement of the cervical glands, which they attributed to venereal disease, the family of the patient that was so treated, seeing grave symptoms supervening, wished to have the advice of a somnambule. The writer was called to attend this consultation, and did not fail to profit by this new opportunity to add to what the Commission had seen. He found a young woman, Mrs. La C., with the whole right side of her neck profoundly engorged by a great mass of glands lying close together. One was open, and from it issued a yellowish purulent matter.

"Miss Céline, whom Mr. Foissac magnetized in the presence of the writer, put herself in rapport with the patient, and declared that *the stomach had been attacked by a substance like a poison;* that there was

[1] "Without attaching great importance to this singular coincidence of the somnambule's prescribing the use of the milk of a goat rubbed with mercurial ointment, and the prescribing of the same by Mr. Dupuytren and the writer, the Commission must in its Report note it; it is presented as a fact the authenticity of which the writer guarantees, but of which neither he nor the Commission can give any explanation." [Note by the Secretary of the Commission.]

slight inflammation of the bowels; that there was *in the right upper part of the neck* a scrofulous malady, which must have been more extensive than it was then; that by the adoption of a soothing treatment, which she prescribed, there would be betterment in two or three weeks. She followed this treatment for a little while, *and there was a notable improvement.* But the impatience of the sick woman, who found the return to health not speedy enough, determined the family to call another council of doctors. There it was decided that the patient should again be subjected to mercurial treatment. The writer thereafter saw the patient no more, but learned that in consequence of the administration of mercury *she had had very serious stomach troubles*, which carried her to the grave after two months of great suffering. A minute of the autopsy, signed by Messrs. Fouquier, Marjolin, Cruveillier and Foissac, showed that there was *a scrofulous or tubercular engorgement* of the glands of the neck, two small cavities filled with pus, resulting from the discharges of the tubercles at the top of each lung, and that the mucous membrane of the great cul-de-sac of the stomach was almost entirely destroyed. These gentlemen ascertained, further, that there was *nothing indicative of venereal disease, whether recent or of long standing.*"

The report ends with these conclusions:

"1. That, in the state of somnambulism, Miss Céline indicated the diseases of three persons with whom she had been put in rapport.

"2. That the declaration of one of these, the examination made of another, after three punctures, and the autopsy held on the third, were found to agree with what the somnambule had declared.

"3. That the several treatments prescribed by her are not of the class of remedies that she might have known, and not such as she might reasonably be expected to recommend.

"4. That she applied them with some discernment."

Mr. Foissac had the luck to be able to keep his word.

We may imagine the emotion produced in the Academy by the reading of the report, only a few pages of which we have quoted. Seldom has so impartial, so clear, or so discreet an account been given of so great a number of observations.

Applause was frequent, but when the question arose about printing the report, members began to have fears for the prestige of the Academy.

"Were most of the things recounted in this report real facts," said Mr. Castel, "they would upset one-half of our physiological knowledge, and it would be dangerous to propagate these facts by means of the press." The Academy had almost decided to follow this advice when Mr. Roux had the happy thought to propose a *via media;* hence the report was not printed, but it was autographed.

It will be readily seen that despite a seeming exactitude "confirmed by the autopsy" in determining the lesions, this exactitude has regard only to the general functions, and that the remarks we have already made, as well as those of Dr. Bertrand, lose none of

their value. It is not *vision of the organs* that the commission found, but a sympathic perception, more or less precise, of the ailments of the patients. I remark further that these consultations of Miss Céline are slightly different from those of other somnambules already mentioned. *She does not suffer the pains and aches she is examining;* she simply perceives them as though they were something palpable; she *feels of them* (*tâte*), so to speak, but does not "catch" them. We shall see further on that this difference springs from the existence of two slightly different types of somnambulic perception. But the basis is the same, and it is always constituted by a possibility of nervic transmission; only we must distinguish between imitative or imaginative transmission, which has no relation to mental suggestion, and *physical transmission*, which serves as the basis of mental suggestion, and which may be more or less pronounced.

"Most somnambules," says Dr. Charpignon,[1] "feel the pains of the persons with whom they are put in rapport. This sensation is transitory, and leaves no trace on awaking if we take care duly to break the rapport. *If it is the magnetizer that suffers, the sensation is most vivid*, and often persists after awaking. If one in a state of ill health goes on magnetizing for several days, these impressionable somnambules become affected with the same complaint. Hence we must be very careful with regard to this point, and must exercise this prudence even with respect to psychic affections, for one can hardly conceive how serious is the influence of an agitated mind upon some somnambules. This identification [he adds] of the two nervous systems produces sometimes the phenomenon of imitation, so that if the magnetizer uses his handkerchief, or coughs, the somnambule repeats the acts; if he takes snuff, the somnambule sneezes; prick the magnetizer or give him a burn, and the somnambule feels the same pains in the same parts of the body."

In this passage three different phenomena are confounded:

1. Imitation of movements—a subject studied of late by Heidenhain.

2. Hyperæsthesia of the sense of smell (the magnetizer takes snuff, the somnambule sneezes).

3. Transmission of sensations.

But evidently in practice these phenomena are usually associated, and that constitutes one of the difficulties of experimentation, and is at the same time a pretty strong argument for the theory of "sympathism," as we shall see.

This word *sympathism*, employed sometimes by Charpignon, seems to me well chosen, and I shall accept it, giving to it, however, a more precise meaning. I will use it to signify the phenomenon of direct and instantaneous communication of the sense of pain and of other subjective sensations, of feelings, and of emotive states; but not

[1] "Physiologie, Médecine, Métaphysique du Magnétisme," p. 72.

facts of observation through eye and ear; these might be comprised under the term "mimism."[1] Mimism, as related to diseases and to acts, will take the name of *psychic contagion*, while facts of disease-transmission (which is nearly always mediate and retarded) by touch alone, unbeknown to the one who undergoes the action, may be considered as coming under the head of *nervic contagion*, properly so-called, or *physical* nervic contagion.

Physical sympathism may be subjective or objective. It is subjective in somnambules who themselves feel the symptoms they discover. In Miss Céline and in the two following cases observed by Dr. Pigeaire, it was objective only.

10. "The lady put her hand in that of the somnambule, who forthwith said: 'Madame, you have a headache?' 'That is true,' the lady answered; 'since this morning I have had a pain in the head.'"[2]

11. "Some time after, Prof. Lallemand told me that a patient wanted to consult a somnambule. Wishing to be assured of the existence of this magnetic faculty, which, so to speak, senses ailments, we know not how, I once more tried my somnambule. [Pigeaire's own young daughter.] Hardly had she touched the sick man's hand, when she said: 'Your legs, sir, are dead-like.' 'Tell me,' said I, 'are you a paralytic; can you not move your legs?' 'No, sir.' 'You were ill after your coming to France,' added the somnambule, 'but now you are much better.' The old man made a sign of affirmation" (p. 61).

12. "Mrs. Ch. had for some time been suffering in her left jaw . . . The lancinating pains were concentrated in the temple and in the branch of the lower jawbone. The patient indicated the track of the pain, and the track was along the dental canal. The somnambule taking Mrs. Ch.'s hand, brought her own hand to her own face, touched with a finger the dental nerve, then the temple and the jaw. At last she said: 'This nerve (the dental) is attached to a blood vessel (the dental artery); it is the same here (at the temple). Well, the vessels are so distended with blood, and their tissue so inflamed, that they compress the nerves and irritate them.'"[3]

This last observation presents an intermediate type. The somnambule does not suffer, but yet she seems to feel the effect of the consultation, since it is *upon herself* that she shows the track of the pain.

Two observations with which we are already familiar, that of Mrs. R., who clearly defined the ailments of one of my patients, selected purposely for this test [p. 32, *supra*], and that of Mrs. B., who divined Mr. Marillier's complaint [p. 95, *supra*], belong to the first category. These two somnambules felt distinctly in themselves the ailments diagnosed by them, and I remember another consultation of Mrs. R.'s, after which she took a full quarter of an hour to recover from an illness communicated to her by a patient. In the course of a few

[1] The author uses here the hybrid and bastard word "imitatisme."—*Translator.*

[2] J. Pigeaire, "Puissance de l'Électricité Animale," p. 61. Paris, 1839.

[3] Charpignon, *op. cit.*, pp. 251, 252.

minutes her abdomen became hard and swollen, as happens in cases of hysteria. Almost of a certainty, had she been awakened at that moment, the ailment would have persisted many hours.

I add that then for the first time did Mrs. R., magnetized by me, make a diagnosis in the somnambulic state. She was in the habit of doing so in the waking state. One might say that in somnambulism she is *too sensitive*.

But as there are somnambules that recognize the ailments of patients without appearing to be affected by them, it is well to examine what the process is that guides them, and to this end I must touch on a phenomenon not less extraordinary, which, for a long time, I durst not publish.

CHAPTER II.

SYMPATHISM AND CONTAGION.

SOMNAMBULES of the second category are not satisfied with "entering into rapport" with the patient by touching his hand, or simply by remaining a few moments in his presence, as is often the case with Mrs. R.: they touch the patient at sundry points, and pass their hands over his body, intent upon what they are doing. Can it be that this performance gives them any indications as to his pathological state?

That is the question. Its importance is seen; for could it be proved that on the surface of the body, and even at a certain distance, ailments more or less deep-seated manifest themselves in a way as yet unknown, science must seize upon so valuable a discovery, and seek to profit by it.

Now, for the first time, do I venture to speak of this phenomenon, though I have known it five or six years. And here is the history of my opinions:

Some seven years ago an old magnetizer, who was no longer in practice, for he was himself a sufferer, said one day to me: "Are you not afraid of doing yourself hurt by magnetizing so many people?"

"Why should I? I am always in good health and can stand a good deal of fatigue."

"I was not thinking of fatigue," said he. "But you take to yourself all the emanations of the patients, all the *morbific fluids*" (*fluides malsains*).

I laughed in his face. I did not believe in his "fluid," nor do I yet. But now I do believe in a certain physical action, whereas then I confounded magnetism with hypnotism, as people do to this day.

It is true that at that time I magnetized very few sick persons, hardly any at all; I made my experiments on healthy persons, and not till a few months afterward did I come to recognize the therapeutic value of magnetism, and undertook to make research in that direction.

But during the whole of the following year, though I magnetized many a patient, I observed nothing of the kind the magnetizer had spoken of, nothing such as I remembered to have read of in certain books, giving no credence at all to the stories.

In fact, it was not upon a sick person that I made my first observation of this kind. We were in the country. The Count de P., who had witnessed my experiments with peasants, asked me to make trial upon him.

I was unable to endorm him, but he believed he felt several very definite sensations. I did not speak a word to him, so as not to influence his imagination, but I, too, while magnetizing him, had a very peculiar sensation in my hands, never observed by me before—*a breath of cool air*, very distinctly felt when I held my hand above his at the distance of a few centimeters, or when I passed my hand about over his body. This sensation was not always of the same intensity, but sometimes, now and then, it was so distinct that it was like a person's breath blown between my fingers. Once the count exclaimed, "Oh, what a funny current!"

Only on finding that my sensations coincided with his, did I acquaint him with mine, and we spent many hours in studying them.

I must mention that the count, though in good health, had just passed many sleepless nights with his cousin, who was seriously ill, and that he was very much exhausted. It was in order to recuperate from this fatigue that he had come into the country.

The sensation I felt much resembled another one that was familiar to me. Any one may experience it by bringing the hand near to an electrostatic machine in action, but not so near as to receive a spark. But in spite of this analogy, I was inclined to think that it was nothing but a rapid absorption of heat, though I was aware that the phenomenon was not always in proportion to the temperature of our hands. At the same time I thought it might be all a subjective illusion, and now I regret my skepticism of that time, for because of it I neglected, in that case, as in a few others, to take detailed notes.

But my attention was won, and I began, little by little, to see in this phenomenon a real cause. First I was forced to recognize that it is *more or less independent of heat.*

I had a patient, anæmic in the highest degree, who always found my hand hot, even when it was numb with cold (it was winter), while she gave me a sensation of cold, despite the heat of her skin upon direct contact.

Another patient, a man, who was also highly anæmic, gave me the same sensation, and in this case there was actual loss of heat, for my hands became very cool in a few minutes.

Usually the contrary is the fact: my hands grow warmer during magnetization and I have a distinct feeling of *dryness*, not always in direct proportion to the actual dryness of the skin.

Still another patient, a man suffering from phthisis, caused me the sensation of a cool draught, but only from the level of the lungs; and an ataxic patient had a cold sensation in the left side, a hot in the right. The magnet produced exactly the same effect (without any distinction of poles), whereas I felt nothing. Finally, in other ataxic patients the case was reversed: they felt nothing, while I had a very clear sensation on one side, for one leg of the patient *drew*, as it were, a current of air from my hands (either hand), while the other leg did not draw at all, or did so less sensibly.

By degrees I found that this phenomenon occurs in many other persons, sick or exhausted, and thus I am sometimes able to determine the degree of exhaustion of a single organ even. I must add that when there is complete paralysis of long standing, I feel nothing—at least so it has been hitherto—and that sometimes the sensation is lacking despite exhaustion.

I have made some very curious observations on the feeling of a breath or faint current of air restricted to the track of *a single affected nerve*, but I have not yet arranged the facts in logical order.

But then, to make amends, I have found another kind of sensation that has given me more positive results. I have relieved hundreds of persons of headache by simple imposition of hands. Simple though the process is, the phenomenon is complex, and I have no intention just at present to theorize upon it. Still, two things are certain: 1, that by this method (which is as old as the world) I remove the headache in 60 cases out of 100 within a few minutes; and 2, that very often I can tell the precise instant at which the pain grows less and disappears under my hand.

And this is how I notice the change: The aching head may be hot or cool, and everybody knows that headache may be produced by several different causes. But independently of these differences, one character, perceptible only to him who holds his hand upon the head, and who is in the habit of observing, is almost constant, to wit, *a sensation of increased warmth under the hands* if the pain is disappearing, but *a lack of this sensation if the ache continues.*

This phenomenon may be observed not only in the head but over the whole surface of the body, and particularly at the epigastrium. If a given surface of the skin overlies a sound organ, the subjective sense of increasing warmth should begin immediately after the imposition of the hands, and should attain maximum after a few minutes.

Some persons to whom I communicated this observation have more or less easily confirmed it; but I cannot guarantee that the phenomenon will, with everybody, present the same character or the same definiteness. I would add that, acting without contact, at the distance of a few centimeters, I sometimes obtain the same results and the same sensations.

As I am not writing a medical treatise, I pass over details and exceptions, and merely remark that henceforth it becomes theoretically possible to diagnose an invisible malady by the touch of the hand. This power may depend simply on a *heat reaction* hitherto overlooked in medical thermometry. The details I have given will, perhaps, have some interest for Professor Grasset, who has just published an essay on the *rapidity* of the action of animal heat upon a thermometer as a diagnostic character,[1] and who holds that "the emissive power, often in contradiction to the patient's temperature, is, on the other hand, proportioned to the sensation had on touching the body."

We know what close relations subsist between certain diseases and the peripheric temperature; Mantegazza's studies show that, as a rule, pain reduces the body's temperature; Mr. Charcot's researches have taught us to distinguish cerebral hæmorrhage from softening of the brain, simply with the aid of thermometric readings; and Mr. Williams asserts that he can tell from the degree of temperature observed to what category of patients an idiot belongs. Even Hippocrates declared that "the expired air that issues cold from the mouth and the nostrils is a death sign," etc.[2]

If it is so as regards rough general indications, it becomes probable that more detailed, more specific *indicia* might give a more or less exact idea of the pathological state of the organism—the more because the thermometric signs do not stand alone. Electric reactions come of necessity into play, and the already old observations of Frank, Nieszkowski and Sniadecki prove that some hysteric subjects are conscious of them. I have, myself, made some researches on this point, but cannot yet state the results with precision. These questions are too obscure, though some physicians think they find in electric reactions the principal causes of diseases.[3]

A subject a little better known, and one closely connected with the diagnostic of diseases by somnambules, is that of *odoriferous material exhalations*.

We must not be led astray by appearances. Somnambules seemingly employ only the touch or tactile transmission from a distance,

[1] "Un Nouvel Élément de Thermométrie Clinique." Pub. in *La Semaine Médicale*, August, 1885.

[2] A detailed analysis of these questions will be found in Redard's "Etudes de Thermométrie Clinique." Paris, 1874.

[3] *See* Scoutetten, "Évolution Médicale, ou de l'Électricité du Sang," etc. Metz, 1870.

but I have repeatedly found that they are also guided unconsciously by olfactive sensations. Cut them off from these, and you will in many cases see the appreciation and communication of symptoms sensibly lessened. Smell is the unconscious's own sense, just as sight is the sense of the consciousness, and touch their common master.

Civilization has suppressed in us the science at once deep and wide which animals possess, and for which they are indebted to the sense of smell; but somnambulism and certain morbid states give it back its true value. We must not forget that if the hypnotized subject can remain insensible while inhaling ammonia, he may also, a moment later, distinctly sense the odor of apples by sniffing at several yards' distance the paper in which apples were wrapped some days previously. Now, it is certain that our individualities, our pathological states, our feelings even, betray themselves by a specific odor which we do not knowingly perceive, but which none the less acts upon smell, leaving on the brain unconscious traces *that in turn associate themselves with the state that produced them.* And by virtue of the law of psychic reversibility, the sensation *a*, belonging to the state A, may reproduce the latter, just as the state may reproduce the sensation. (*See* Part III., Chapter viii.)

That which is quite easy in a state of exceptional exaltation of smell and *exclusive concentration of the attention* upon one object ("rapport"), of course, is hardly possible in the normal state, and sometimes incomprehensible. But it is not to be forgotten that, as Dr. Monin says in his remarkable semeiological monograph,[1] "Odorant waves always reveal important chemic changes . . . and *in all biological phenomena* play a leading part."

Most diseases have their specific smells, and these, by marking the stage of the pathologic evolution, may even guide us often to a sure prognosis. "In the chamber of a lying-in woman, the sour smell betokens to the practiced nose that all is going on well, that the work of milk secretion is beginning. On the contrary, an ammoniacal smell will make the physician fear the imminence of the morbid syndromus known as puerperal fever." Dr. Vidal, of Cassis, records in his "Treatise on Surgery," that J. H. Petit, while traveling in Germany, distinguished *the smell of gangrene* among other smells not less disagreeable, and so was able to cure a man dying of strangulated hernia (p. 6). The cutaneous perspiration and the various secretions of the skin diffuse round about each individual a special odor. This odor, commonly but little sensible, is very distinctly sensed by certain persons of highly developed sense of smell. Cadet de Gassicourt ("Dict. des Sciences Méd.," vol. iv., p. 196) tells of a young matron who by the smell alone distinguished men and women. She could not endure the smell of her bed clothes when touched by any one but herself.

[1] "Les Odeurs du Corps Humain," p. 4. Paris, 2d ed., 1886.

The *Journal des Savants*, 1864, relates that a monk in Hungary could by olfaction tell a chaste woman from one not chaste. Perty cites many cases of this kind. It appears that the Cardinal Alexander Albani, after losing his sight, distinguished by olfaction young women from old.[1] Debay reports an observation of a somnambule who, after examining by smell a score of different objects, apparently inodorous, as rings, pins, brooches, etc., belonging to ten different persons, sorted them and distributed them to their owners without making a mistake.[2]

It is even not impossible that certain psychic states may reveal themselves in the same manner, for certainly the odor of the cutaneous exudations undergoes marked changes under the influence of sundry emotions. Says Dr. Monin:

"The action of the nervous system on the odor of the cutaneous exudations is highly important; not infrequently it is heightened or modified by moral excitement, depressing passions, and neuroses. Gamberini (*Annali Universali*, 1854) cites the case of a young man, who, in consequence of being crossed in love and of a violent fit of jealousy, gave out from his whole body a fetid smell, nauseating and very lasting. Dr. Hammond, of New York, lately reported (*Med. Rec.*, June 21, 1887) the case of a young hypochondriac whose skin gave out the odor of violets; of a victim of chorea who exhaled the odor of pines; of an hysteric woman, who, in her crises, emitted the smell of bananas; he tells of another hysterical woman whose transpiration was restricted to the left anterior half of the chest, exhaling the odor of iris. In the latter case a chemical examination of the sweat was made and showed the presence of butyric ether."

I have myself observed an hysterical woman in whom the approach of a paroxysm was announced by an odor of Gruyère cheese, or rather by an odor that recalled the taste of Gruyère. In another case a metalloscopic plate of tin applied to the patient for a few days acquired a very strong smell resembling that of petroleum, despite the patient's scrupulous neatness.

"In *localized perspiration* (continues Dr. Monin) these odd osphresiologic anomalies are by no means rare. Schmidt knew a man subject to a hyperhydrosis limited to the hands, and who smelt of sulphur. Orteschi observed a young girl who without any trickery gave out a strong odor of vanilla from the commissures of the fingers. All these phenomena result from disorders of innervation. According to Hammond the *odor of sanctity* is not a mere rhetorical figure, it is the expression of a holy neurosis[3] perfuming the skin with effluvia, more or less agreeable, at the moment of the ecstatic religious paroxysm" (p. 17). "In lethargy (which hardly ever occurs in hysteric subjects[4])

[1] Perty, "Anthropologie," I., 187. Leipsic, 1874.

[2] A. Debay, "Hygiène des Douleurs," p. 32. Paris, 1877.

[3] *Sainte nevrose* is Dr. Monin's rendering of Hammond's phrase, whatever that may have been.—*Translator.*

[4] Or rather in *hypnotizable* subjects.

the cutaneous exudation emits a cadaveric smell, thus adding to the picture of death, already so realistic. This odor must doubtless have been the cause of frightful mistakes: such at least is the opinion of Bernütz."

According to the researches I have made in cholera times, hypnotizable persons constitute the greater part of the quickly fatal cases; but such persons are the ones liable to fall into *true lethargy* (profound paralytic aideia), presenting all the appearances of death. It would be well, therefore, in such cases to have recourse to magnetism, which might transform this state into somnambulism; or to call in a somnambule who presents the phenomenon of sympathism, and who doubtless will know better than we how to distinguish apparent death. At all events one must not laugh at this means before one has tried it.

As the different mental states find expression by means of a trophic action of the nervous system, they may produce a special cutaneous odor. The odor exhaled from the skin in mental diseases, an odor noted in 1862 by Dagonet, has been studied particularly by Fèvre of Toulouse in his work "Les Altérations du Système Cutané dans la Folie" (Paris, 1876). He there says (p. 19):

"The sweat of insane persons has special *sui generis* emanations, penetrant and infectant, like those of hands that are kept constantly shut, something like the smell of mice or of the fallow deer. This smell is found especially in general paralytics and confirmed dements.[1] It impregnates the clothing, bedding, furniture, as well as the rooms occupied by the insane; and it is very lasting, in spite of soap and water. This odor is so characteristic in simple insanity (*folie*) that Burrows declares that were he to find it given out by any one he 'would not hesitate to pronounce the person insane, even if there were no other evidence.' An English psychiater goes further: Knight declared that he could detect pretended insanity by the absence of this physiognomic odor."

This pathological exhalation may even be localized and may occupy a region of the skin corresponding to the inward disorders. S. Weir Mitchell has noticed that in nerve lesions the corresponding cutaneous region emits a smell resembling that of stagnant water. Mr. Monin is of the opinion that in such cases we have an epithelial dystrophy rather than actual changes in the physiological secretion—but that is no reason why an hyperæsthesic sense should not be able to detect by this means the state of the disease and its area.

That most *occupations* may have their specific odors we can understand. Mr. Monin sees nothing out of the way in the saying of the famous Vidocq: "Place me in a crowd and there I will pick out from among a thousand a *galley-bird* by the smell alone." Chomel

[1] French *dément*, Latin *demens*. The meaning is plain—a victim of *dementia*.—*Translator*.

observed for six weeks a groom suffering from pneumonia, whose sweat retained during all that lapse of time the smell of the stable.[1] Again, Monin writes:

"In enuresic patients, a urinous smell, or a mousy smell, penetrant and which nothing can suppress, has often been of use to military surgeons in detecting the simulation of incontinence of urine. So, too, in constipation there is an odor from the skin like that of fæces; often we have found that this odor perceived by the patients, contributes to bring on hypochondria, which is ever lying in wait for sufferers from this complaint" (p. 25).

In gout the skin secretions take a special odor, which Sydenham compares to that of whey. In jaundice the odor is of musk; in oppilation, of vinegar; in syphilis, of honey; urinous in urinary disorders (cystitis); of sour beer in scrofula (Stark *apud* Hebra); of warm bread in intermittent fever (Heim); in diabetes when there is perspiration the smell is of hay (Latham), or rather of acetone (Picot), but according to Bouchardat, midway between aldehyde and acetone, being due to mixture, in variable proportions, of these two bodies. In cholera the odor is ammoniacal (Drasch, Parker); it is acid in what is called milk fever; sweet in the onset period of the plague (Diemerbroeck), or honey-like, according to Döppner, who observed the plague at Vetlanka (*Lancet*, February 1, 1879); aceto-formic in rheumatism, particularly in the region of the engorged articulations (Monin); of new-plucked feathers in measles (*rougeole*); of new-baked bread in scarlatina; in small pox the odor is that of the fallow deer; in typhoid fever it is that of blood (Béhier). Frederic Bérard goes so far as to say that, apart from the secretions, the cutaneous odor *draws flies to a still living body.* However little noticeable it may be, it says plainly that death is near: a sweat having a cadaveric odor *precedes* death, says Bœrhaave (Aphorism 728 of the *editio princeps*). Dr. Althaus tells us that Skoda hardly ever was led into error by this indication, and Crompton, of Birmingham, also laid great stress upon this as an important clinical symptom. But the smell given out at the death agony is totally different from the death-odor: it is universally admitted to be specific, and it differs entirely from the odor of putridity.[2]

It would be difficult to insure the exactitude, or, at least, the practical value of all these assertions. But they suffice to show that there is ground in facts for the occult judgments of somnambules, not only from the diagnostic, but also from the prognostic, point of view. Clearly, disease is not bounded by the surface of the body; it goes beyond it.

The reader, doubtless, has heard tell of extraordinary diagnoses made by somnambules at a distance, by means of some object belonging to

[1] Monin, *op. cit.*, p. 25.

[2] Monin, *op. cit.*, p. 27.

the patients, especially by means of *a lock of hair*. Why by a lock of hair in particular? Perhaps because the hair, because of its odors, manifests better than any object the patient's pathological state.[1] Dr. Charpignon cites many facts of this sort, and, like all magnetizers, attributes this form of transmission to the *magnetic fluid*. These facts I do not bring forward here because I have never had cognizance of anything of the kind. Once only, some fifteen years ago, wishing to experiment upon this point, I took a lock of my grandmother's hair and handed it to a somnambule. She told me that it belonged to a beautiful lady with whom I was in love, and that my love for her had not cooled much of late. True, my grandmother's hair, despite her age, is still black. This somnambule, like all extra-lucid somnambules, had her "professor," who turned her doings to profit for himself. To make sure of her lucidity, usually he did not endorm his subject; he simply bandaged her eyes, which gave to the consultations an air of serenity. But the woman was sensitive and well endormed when I consulted her. Her state, however, was one in which sensibility offers nothing out of the common. She would doubtless have divined better in the waking state.

So I have not verified this phenomenon, but it appears to me to be not at all impossible. The hair itself possesses an odor peculiar to each individual, and which varies according to sex, race, age and pathological state. We are told that the hair of the Chinese retains its musky odor even after it has been washed with potash (Galippe, paper read at the Société de Biologie, January 25, 1879). "Hairdressers [wig makers?] can tell easily," says Mr. Monin, "simply from the smell, whether a bunch of hair was cut from the head of a living person, or whether it is made up of hairs that have fallen out."

There are also wide differences with regard to the tactile sensations produced by a bunch of hairs. Their thickness, their elasticity, their smoothness, the rustle they make when rolled between the fingers, vary widely. And there is no doubt that there subsists a very close relation between the quality of the hair and the psychic states. Everybody knows the injurious effect of grief, which may be produced in a very short time. I have observed in myself that my hair becomes less supple under the influence of worry, softer under agreeable conditions. Gratiolet makes the observation that melancholy makes the skin dry and, consequently, the hair too.

At the same time the odor changes perceptibly with the dominant state of the nervous system. "In hysterepilepsy," says Monin, "the

[1] Dr. E. Louis de Séré prefers a shirt or a flannel vest that has been worn by the patient. In his book are found thirty-five more or less extraordinary observations of this kind. Its title is "Application du Somnambulisme Magnétique au Diagnostic et au Traitement des Maladies." Paris, 1855.

hair, at the moment of the paroxysms, has a special odor, always the same, resembling the smell of ozone, or of an electrical machine operated in dry weather" (p. 33).

Hence, it may be that a hyperæsthesic sensibility can detect in a lock of hair a certain number of true symptoms. "But," some one will, perhaps, say, "your whole explanation is rather obscure. A somnambule may have sensations that we never receive; nothing more likely than that. But to find the smell of ozone in a lock of hair and to divine hysterepilepsy, are two things. So with regard to all the other objective explanations. It remains yet to be proved that somnambules *know the meaning of these signs.* Granted that each disease, each emotion—why not each thought?—is manifested outwardly by a modification of our material emanations: that is quite possible; but the bond that connects these modifications to these states, the inmost relations between them—where may the somnambule learn these?"

I answer: First, we must not exaggerate the phenomenon we are trying to explain.

Sympathism exists, but it is a rare fact. In a hundred somnambulic diagnoses you will hardly find a dozen that are entirely exact. That suffices to exclude the hypothesis of bare chance, but it does not suffice for the formulation of a simple, precise theory, always applicable. It is not well to prove too much, and to make that appear simple which is not simple. We must allow a little for chance, for natural acuteness, for involuntary suggestions, for the vagueness of most sympathic communications. Then the difficulty of finding a causal bond between a sensation felt and its physiological meaning is not so enormous as it seems. That bond exists, and it is formed in this way:

Our experience is twofold: conscious and unconscious. The latter is the larger—by far the larger; it is the first, has a basis in heredity; it is ever growing richer at the expense of conscious experience; it is ever insensibly completing the latter by generalizations, impulsions, presentiments. We have much more in our brains than we suppose—much science we little think we have; and Socrates was right when he said that we give birth to ideas, but do not create them. Ask a man what was the color of the walls of a room he lived in last year—he will, perhaps, be stalled; but take him to that room and he will readily see whether any change has been made. You may fail to recognize an old friend, but his face will, perhaps, suggest to you a series of recollections. You have never thought of defining the "cutaneous odor" of a loved person, but a like odor will make you think of her, and you will not even know why. What one of us has not been for a longer or shorter time with a number of sick persons that exhaled an odor or exerted some other sort of action upon us,

that to us was entirely unconscious? But nevertheless there was then formed in our brains a close association between the presence of a sick person and that particular reaction. We do not feel our own cutaneous odor, but were it to be changed suddenly we should surely note the difference. And these associations are ever forming, and they persist. We are not aware, but our unconscious knows very well, that in a moment of fear, joy, pain, hope, anger, love, as well as in pathologic states that we ourselves have been in, our individual atmosphere changes, and, recognizing this change in another individual, it may infer these several states, and even may, under exceptionally favorable conditions, make them sensible to ourselves. Now the conditions can nowhere be more favorable than in the state wherein:

1. All extrane sensations are shut out;
2. The attention is wholly set in one direction;
3. All the senses may be in a state of exaltation.

And if sometimes sympathism attains a surprising degree of force, if the symptoms we discover appear in ourselves, or rather reveal themselves by this apparition, that, again, is an effect that is not of necessity physical; it, too, may be the product of a psycho-nervic reflex action. But to understand it we must know that the *association theory*, as set forth in psychology, is very incomplete, in essential particulars incomplete. Psychologists think they have said all when they admit associations between thoughts, feelings, sensations, volitions and movements.

Well, if that were all, our psycho-physical mechanism would be utterly incomprehensible. We could not even tell why these associations are not a dead letter, why they live and are operative. Bain long since felt the necessity of postulating an *involuntary energy* beyond the known associations. The theory of association is not false; it is only incomplete. Psychological association is but a special case of biological association in general, and physiology will not be a comprehensible science—one comprehensible in its details—until we apply to it the same association principle that has been of such service to modern psychology. We will here dwell upon only one point of this application: there are associations between ideas (emotions, sensations, etc.), but there are also associations between ideas and states that seemingly have nought to do with psychology—bodily, organic states: there are ideorganic associations.[1] An idea may be associated with an inflamed finger, a skin secretion, a paralysis of the right arm, a sore on the left jaw, the quantity of adipose in the tissues, a neuralgia, an attack of cholera, of rabies, and so on; and these associations may be so definite and real, that, as the thought of Peter produces the thought of Paul, the thought of an hæmorrhage shall produce hæmorrhage, the thought of a cicatrization produce cicatrization, of a disease that

[1] *See* Appendices II. and III.

identical disease. I have seen hæmorrhages stopped by the act of the imagination ; I have seen sores healed rapidly by suggestion ; I have seen a fat hysteric woman grow thin in the course of a few weeks by somnambulic order ; I have seen cases of cholera brought about simply by thought-influence, apart from any epidemic action.

Hence, it is nothing surprising if the recollection of some ailment should itself produce that ailment.

Finally—and here ends my answer to the objection stated above—I do not at all intend to explain everything by one theory. A theory that is simple is rarely a correct theory, particularly in biology, particularly in hypnotism ; and the tendency to refer unknown things to things known must not blind us to new and complex facts. Objective sensations, unconscious perception, ideorganic associations do not account for *all* the facts of sympathism and nervic contagion. We must have the courage to make that confession, and must look in other directions.

I have already mentioned the sensations the magnetizer sometimes feels on touching the patient. I was not the first to observe them. There is nothing new in "hypnotism"! A hundred years before me, these sensations were discovered and studied with special care by a physiologist and physicist now quite forgotten. His name was De Bruno, and he was the introducer of ambassadors to the Count d'Artois, brother of the King of France. His first book was on mineral magnetism ; then, Mesmer's "animal magnetism" having attracted his attention, he devoted himself, 1785–1805, to a series of original researches, the results of which would have filled two volumes. He died in 1818, leaving them unpublished. At that period, animal magnetism having been discredited by the legitimists of science, the family of the deceased did not care to authorize the publication of the work ; it was handed over to the Société de Magnétisme and appeared only in extracts under the name of Mr. de Lausanne.[1] This book had but a feeble echo. It was the further extracts quoted by Mr. Aubin Gauthier[2] in his "Practical Treatise" that made it a little better known, though without rescuing the author from oblivion.

There are extraordinary things in Bruno's experiences that I cannot guarantee. He himself, it seems, had great sensibility, and perhaps "complementary imagination" was not altogether a stranger to him ; but as there is a certain analogy between his observations and mine, albeit I am not at all hypnotizable, I will give a few quotations:

"If Nature (says this author) has endowed the one who magnetizes with a nerve sensibility of some little delicacy, he *will feel externally* many of the irregular movements that take place in the

[1] Lausanne, "Des Principes et des Procédés du Magnétisme," etc. 2 vols. Paris, 1819. The first volume contains the extracts from Bruno.

[2] A. Gauthier, "Traité Pratique du Magnétisme," etc., pp. 233–289. Paris, 1845.

magnetized person ; *sensations* will be for him sure indications of the work that Nature, aided by his action, is doing in the patient. It is true that all persons are not gifted with this sensibility, and that *it is not always of the same degree of delicacy in the same person;* but some there are to whom this property becomes sometimes burdensome ; and there are others who, in a state of crisis, have such sensibility as renders incredible the degree to which the delicacy of their organs makes them capable of distinguishing. To my natural organization I must refer a sensibility *that has been perfected by the habitual use* that I make of this property of my senses. I owe much to this use and to the attention with which I note my sensations. Were everybody to do as much, this property would become very common, and there might be developed in some individuals a delicacy of sensations that would seem far more extraordinary still than anything I may report about my own in the sequel" (pp. 86, 94).

Let us observe, in the first place, that we find in Mesmer the following passage: "Touch *at a little distance* from the part is *more powerful*, because there exists a *current* between the hand, or the conductor, and the patient. . . . . We observe the *flow of a matter* (*écoulement d'une matière*) the subtility of which penetrates all bodies" (Prop. xxiii).

It is perhaps this subjective sensation that led him to adopt the theory of a *fluid.*

"There is no doubt," says Bruno, "that Mesmer formally designated the currents (he even gives them a special name—*tonic currents*), and that he recognized their existence ; but there is nothing to show that he explained the subject to his disciples."

Bruno distinguishes *sensations of currents* from *entrainments* (attractions) of currents. Apart from the sensation of a current, he further believed that he felt *attractions* toward certain parts of the patient's body. He communicated these experiences to Dr. Deslon, who noticed something similar on holding the hands an inch or two away from the stomach of a patient. He felt peculiar sensations "in the flesh around the root of the nails."

"The sensations (says De Bruno) vary according to the person you magnetize. You feel, for example, that the breath (*souffle*) that blows upon your hands is *warm.* This warmth has differences that habit will teach you to distinguish ; the warmth is greater or less, more or less *dry.* Sometimes it makes the hands *dry.* I am accustomed to wet my hands, and not to wipe them ; the current soon removes the excess of humidity. I wet the hands to retain the sensibility, which is reduced by dryness."

It is seen that these sensations are nearly the same as those I experienced before I knew of Bruno's works. As regards the influence of humidity, I made use of it in the Infant Jesus Hospital at Warsaw, in 1881, not to increase the sensibility of my hands, but to increase their curative action (gentle massage) in a very obstinate case of

hemianæsthesia. The thought to do so came to me instinctively, and the effect was very favorable, for the patient's sensibility came back under my hands, and I gained ground far more rapidly than if the hands had remained dry. Four seances sufficed (with the aid of somnambulism and hypnotic metalloscopy) to restore the patient's sensibility.

"In other circumstances (continues Bruno) you have sensations of *cold*, and this cold, too, shows differences. Sometimes there is a very faint tingling at the tips of the fingers; again there is a prickling and a numbness. One experiences also a nervous shudder. A feeling of cold nearly always betokens an obstruction, an engorgement, or some atony" (pp. 76–79). "A dry, burning heat betokens a tension of the fibers; a gentle, moist heat is a favorable symptom, which tells of a freer circulation, and sometimes an evacuation" (Deslon, Aph. 14).

Formication at the finger tips indicates the existence of bile and of acrid blood, especially if it is felt when the head or the arms are magnetized (Bruno, p. 79). The benumbing of the hand, the fingers and their extremities, shows a defect in circulation (p. 77). The magnetizer sometimes feels a *fluctuating* motion in the fingers, which tells him that a movement of the blood is going on (*un mouvement sanguin s'effectue*) in the patient (p. 78). When there is slime (*des glaires*) in the stomach or chest, the fingers seem to become clumsy and stiff; sometimes one feels in the fingers a *circular pressure* as though a silk thread were wound around them (Mainduc, Deleuze, "Instr. Prat.," 342). This pressure sometimes appears as high up as the wrist, which feels as though a bracelet were tightly clasped about it (Deslon, Aph. 10; Bruno, 77). When there is nervous relaxation, the hand is quickly wearied; there is a degree of weakness in the fingers and wrist (Bruno, 78; Deleuze, 343; Gauthier, 11, 12).

Besides these sensations in the hands, Bruno had also sympathic sensations all over the body. "When I am very near and face to face with a patient," he says, "*I feel the reaction of his work*[1] *in the part opposite*, so that an ache in the liver makes itself felt in the spleen, or parts adjacent; and one in the spleen, in the liver. But when I am at a distance from the patient, the pains are felt in the same viscera as are affected. These observations, repeated almost daily for three years, confirm me in the belief that like parts in each individual exert upon one another reciprocal action."

An English author, Dr. Mainduc, quoted by Deleuze ("Inst. Prat.," 342), gives some indications that do not agree always with those of Bruno. For the latter *cold* indicated obstruction; while, according to Mainduc, in obstructions one feels a sensation of acridity, dryness, contraction and formication, if there is no inflammation, and of *warmth* if there is inflammation. Contusions produce a sense of

[1] Physiological work; the work of his organs — *Translator.*

heaviness and numbness in the hand. The presence of worms produces formication or a pinching sensation (*pincement*) in the fingers. In nervous relaxation there is a feeling of weakness in fingers and wrist.

"I know a man," says Deleuze,[1] "who was very closely associated with the one whose work I have quoted. *He feels the disease of those he magnetizes;* he experiences in advance, *and sometimes in a very painful way*, the crises they are soon to have." "I know (says Gauthier) a lady of about 50 years, a grandmother; she has been present at the several child-births of her daughter-in-law; and placing her hands on the seat of the pains, she felt and announced in advance the crises that were about to come" (p. 278).

I shall not go so far; but, as I have already said, by putting my hands on the suffering organ, I can, not always, but very often, tell the moment when the trouble is disappearing, for then it is that I have the inward impression of a gentle warmth, ot a warm shiver.[2] According to Bruno, such a sensation announces that the circulation is in equilibrium. On the contrary, if the hands grow cold, instead of warm, I begin to have doubts of success. "I know a lady," says Deleuze again, "who when she begins to magnetize feels much heat in her hands. After a seance of three-quarters of an hour, her hands become quite cold; she then no longer acts" (p. 334). "I also know

[1] "Instruction Pratique," etc., p. 344.

[2] A lady of my acquaintance whom I taught to magnetize, though without communicating to her the phenomenon in question, being elated by the successful result of her first experiment, wrote to me as follows: "As I announced to you in my last letter, I have, by the aid of the hypnoscope, found three persons of sensibility. One of them is Mrs. A.'s daughter, a girl of 18 years. One day, seeing her suffering from a severe headache, which never lasts less than two or three days, I began by touching her forehead and head, as you taught me to do, and as I learned in the little book "Le Magnétisme Curatif." In ten minutes the ache was over; it came back the next day, weaker, at the same hour, and did not return on the following days. I cannot express to you my gladness and astonishment. But that is nothing compared with what remains to be told. The same young lady has for some years suffered fearfully on the first and the third day of her period. She was suffering in this way a few days since; she was bathed in perspiration and did nothing but cry for pain. The thought occurred to me to try the same means, for all the remedies ordered by the doctors had been without effect. Thinking that anyway this could not do her any harm, I laid my hands upon her stomach and then made passes. In 10 or 15 minutes my patient was sleeping quietly, and she slept for nearly two hours. Upon being awakened she was entirely well, and the third day of the period passed without any pain. Can it be that my action produced this result? I can hardly believe it, for she fairly writhed in agony. Tell me what you think about it. And, strange to say, *I felt the pain going away, as though something was becoming assuaged* [*quelque chose s'apaisait*] *under my hands.* (Is that an illusion of mine?) *I felt a strange pulsation in my hands, and particularly in the fingers.* After every treatment of this kind, I find myself *horribly* fatigued; it was as though I were losing part of my strength. (Is that, too, an effect of my imagination?) Please explain all this to me, and advise me what I am to do in other cases."

several magnetizers who, when they lay their hand upon the seat of an internal ailment, feel a pain extending to the elbow; the hand grows numb and even becomes swollen. This effect grows less with the disease; it ceases with the cure, and this cessation shows that the magnetism is no longer needed." "I have known a physician to experience this sensation the first time he tried to magnetize. In other persons it does not appear till after repeated trials. I have not experienced it myself. Yet some effects that I have experienced under sundry circumstances lead me to believe that I should have acquired it had I taken pains to study the cause that produced them" (pp. 330, 331).

As for me, I never have felt any direct and immediate painful sensations. As an immediate effect, I have often felt simply fatigue, an exhaustion of a peculiar kind not in proportion either to the movements performed or to the emotion or the psychic concentration.

We must distinguish between these phenomena.

The action of the magnetizer in making passes produces fatigue, like all monotonous movements, though they be slow. But this fatigue is something well known; it is muscular fatigue. We can fatigue in this way the arms, but not the legs, for we do not magnetize with the legs, and in most cases of magnetizing persons in good health one has no other sensation but that of fatigue of the muscles.

With novices in magnetism in certain important circumstances, and particularly in dealing with patients that are seriously ill, another sort of fatigue is added to the first—that of exhaustion by emotion.

The sufferings of others cause us suffering through sympathy. Now, every suffering, every painful emotion, causes exhaustion, especially when prolonged. This fatigue is not localized in the muscles. On the contrary, the muscles may be exceptionally excited under the influence of such an emotion. Persons who are feeble and ill regain their strength when called upon to care for a person dear to them, who is ailing worse than themselves. But at last an emotion may produce exhaustion in an instant and give a sense of prostration, of moral fatigue.

Finally, there is still another sort of fatigue, known only to those who have practiced magnetism for a long time. This, too, is an exhaustion, even an exhaustion more lasting than that caused by an emotion, but it is of a different character. This I will call *external exhaustion*, for it produces a feeling as though *the surface of the body* chiefly were fatigued. Especially in the hands, one has a very unpleasant feeling of dryness. The surface of the body seems to us void;[1] we are no more master of the ambient air; it presses upon us and weighs upon us. And this sense of exhaustion, if due to an

[1] In the original *vide*, empty, void, etc. The sense is by no means obvious.—*Translator.*

important cause, is not easily removed. Rest acts very slowly—far more slowly than in muscular or in psychic fatigue. There is only one way of working the miracle of reconstitution, and that is massage.[1]

The state of the hands is sensibly bettered by dipping them in cool water, and the state of the whole body by a vapor bath, but massage is needed for complete restoration. I recommend to all who magnetize many patients these three processes: First, immediately after a magnetization, dipping the hands in water, and in case of need, or from time to time, a vapor bath, then massage.

Once, when in this sort of state, I laid my hand upon the forehead of a patient in somnambulism suffering from headache. She allowed the hand to remain for a few minutes, then put it away without saying a word. "Why did you remove my hand?" I asked: "it always soothes you." "Yes; but it is spoilt."

When, after having dipped my hand in cool water, and taken some rest, I visited her again, she no longer put my hand away. "Why do you allow it to remain now?" I asked. "Because it is *better*," was the reply. She could not tell me what she meant by saying that a hand is "better," "good," or "spoilt," but subjectively I was forced to recognize these differences, for my "spoilt" hand was spoilt for me too, because of a sense of weakness and disagreeable dryness (a subjective impression this, for the hand was not dryer than usual) and of an enervating heat. But the conditions must be exceptional for this effect to be produced in me in such a degree.

The prediction of the old magnetizer was fulfilled for the first time under the following circumstances: I was attending a consumptive patient, whose fulgurant pains came on by paroxysms and lasted for hours. There was only one way of allaying them—imposition of hands. The reader will laugh at the remedy, yet the fact was so, nevertheless. Taking a seat by the bedside of the patient, I laid one hand on his thigh and waited for the thermic reaction. It did not come till after 10 or 15 minutes: the pains grew less by degrees, and at the end of a quarter of an hour, sometimes later, they would end. As for me, I would be quite fatigued.

And yet neither the physical fatigue nor the emotion—I had grown accustomed to these crises—could account for this general sense of

[1] The phenomenon of exhaustion seems to have been observed when the magnetic treatment was first used in France, for Jussieu mentions it in his report to the King: "The treatment, especially treatment by contact, may fatigue those who administer it. I have never experienced this myself, but I have seen many magnetizers, worn out after protracted seances, have recourse to the tub [in the original, *baquet*, a tub of water employed by Mesmer in his seances.—*Translator.*] and to *contact with another man*, and regain their power by the use of these two means." ("Report of one of the Commissioners appointed by the King to investigate Animal Magnetism." Paris, 1784.)

exhaustion. I had not, however, any painful sensation. But the following morning, and sometimes in the night, I used to feel in the back or in the arms pains of a peculiar kind. At first they did not last long, and though they were pretty sharp they impressed me as counterfeit pains, superficial, extraneous. They were but an *echo* of the fulgurant pain of the patient.

This phenomenon was repeated rather often without any injurious effect. I have since then observed other cases where transmission seemed unquestionable—in fact I have observed many cases of double transmission, that is, of transmission to a third person unbeknown to him.

I would catch a headache, say, or some rheumatic affection, from a patient, and involuntarily would transmit it to another, though with decreased violence and with some retardation. A pain thus doubly transmitted I have always been able to remove so that it would not return. Twice only have I observed in myself almost immediate transmission. In the first instance there was nervous aphonia that had to be cured as speedily as possible, for the patient was to deliver an address in public. The voice was restored for the whole time of the address, but I was hoarse for a full quarter of an hour. The second instance was one of cold in the head, which was communicated to me almost instantaneously by one of my patients. She experienced a little relief (though I had magnetized her for an entirely different ailment). As for me, the cold in the head lasted the whole evening, disappearing the next morning. In other cases the "communicated" cold in the head would appear only in the night. I would awake feeling really ill and hardly able to breathe; then I would sleep again, and it was all over.

So curious are these phenomena of *nervous contagion* that it needs a little courage to speak of them; but we must speak of them, for assuredly in this transmission we recognize the *first stage in mental transmission.* Organic states can be transmitted from one individual to another, and hence thought transmission is only a question of degrees, for a thought always answers to a special organic state.

Nervous contagion is a rather frequent phenomenon, provided one takes the trouble to notice it. For me it was an easy thing to find, for ever since my fourteenth or fifteenth year I have been in the habit of observing whatever goes on within myself and the effects produced by different influences. In the meantime I never have been seriously ill, but if I suffer from any indisposition I am able readily to say what is the cause. The transmitted ailments were the only ones that I was unable to refer to any common or ordinary cause, and little by little I was forced to succumb to the evidence and to admit the phenomenon in question.

Still—and this I never have thought of denying—the influence of the imagination may play a part in many of these phenomena.

When you take a headache without any suspicion that the person you are magnetizing has one, and it disappears in him the moment it appears in you, there is reason to infer physical nervous contagion. In most cases the magnetizer knows of the ailment, and if so, then quite likely psychic nervous contagion by ideoplasty is added to the direct action. Here are a few highly instructive facts upon this point, that have been confirmed by the experience of many persons. Several Brussels newspapers mentioned them at the time of their occurrence. The following narrative is written in the form of a *feuilleton* by A. Lebrun, a clerk in the (Belgian) Ministry of Justice, a neophyte in magnetism, and therefore an ardent apostle:

. . . "Another day I met two poets and a prose writer; and as one is required to give names when one speaks of magnetism, I may say that the poets were Messrs. Adolphe Mathieu and Van Hasselt, and the prose writer Mr. Deschamps. The first-named and the last were strong unbelievers; Mr. Van Hasselt was already well along in the road of the faith; he was a catechumen, asking only for full illumination. I noticed my three men right on Carmes Street. I had notified Mr. Montius, the magnetizer; we found him at home, in company with a female somnambule, and he set to work at once. The oddness of the mimicry of magnetism caused the two unbelievers to chuckle. As for Mr. Van Hasselt, he was as solemn and thoughtful as one of Lamartine's "Meditations." Mr. Montius, noticing this, conceived forthwith a favorable opinion of the poet, and wanted to make an experiment upon him. But now the somnambule complained of a violent headache that had come upon her suddenly. Mr. Montius smiled with an air of satisfaction. We asked him why he smiled. 'Why,' he answered in a whisper, 'I gave her that headache on purpose It was now the turn of our unbelievers to smile. But the somnambule having heard what Mr. Montius had said, exclaimed: 'Since 'tis you that gave it me, you can take it away! Take it away, then; I pray you, take it away!' 'One moment,' said Mr. Montius; and applying one hand to the somnambule's forehead and the other to Mr. Van Hasselt's, he made him a gift of the somnambule's headache, she exclaiming with glee: 'Thanks! My headache is gone.' 'Yes, gone, but I have got it,' cried Mr. Van Hasselt, with a woful expression of countenance. The rest of us burst out laughing uproariously, with the exception of the patient, whose pain grew more and more intense. He begged Mr. Montius to make the headache pass to another head. 'Well, here is mine,' said Mr. Deschamps; 'and if you succeed in introducing into it what is in Mr. Van Hasselt's, I pronounce you, not in verse, but in correct and polished prose, a being such as fancy paints, a very wizard!' 'I will try,' the magnetizer answered, 'but I do not guarantee success; unbelief is a force that repels magnetism.' At the same time, raising his arms, he laid one hand on the head of Mr. Van Hasselt, and the other on that of Mr. Deschamps. I observed attentively the face of the latter; the two corners of his mouth, at first kept wide apart by a sardonic smile, insensibly came together so that soon his mouth made a perfect letter O, proving that the serious mood of Mr. Van Hasselt was gaining on our friend. Suddenly he freed himself from Mr. Montius's

hands, saying: 'Enough; I surrender. The devil take me if I haven't an able-bodied headache!' 'Yes, but I am beginning to think that you have all conspired to act a comedy at my expense,' said Mr. Mathieu, who till now had looked on, seemingly meditating deeply. 'Pass my headache to him to convince him,' said Mr. Deschamps to the magnetizer. 'With pleasure,' Mr. Montius replied; so he operated on Mr. Mathieu as upon the two others. Again the experiment was entirely successful, so that the new patient shook his head repeatedly as though to make sure of the tenacity of the ache he felt. He wanted to keep his megrim for some time, for fear lest conviction should vanish suddenly with the ache.

"Such, reader, is the story I had to tell you for your convincement, for, I do confess to you, they that believe in these phenomena have a mania for sharing their conviction with everybody."[1]

It is probable that in these experiments the first transmission—from magnetizer to somnambule—was effected by a physical nervous contagion, but in the cases that follow ideoplasty plays the principal, if not the only, rôle; else the ailment would be considerably lessened at each transmission.

Du Potet, one of the most experienced practitioners, advised his pupils always to magnetize without contact, and the reason he gives is this:

"*Inoculation by Contact.*—Among the facts I have ascertained I may quote these: A woman suffering from a gouty arthritic affection, whose joints had become solidified, whose limbs had lost their flexibility, whose jaws, even, could not open fully, was put in rapport with one of my somnambules. This somnambule, after having seen the ailment perfectly and indicated the thermal waters that would cure it, complained of suffering in the same parts that were affected in the patient. I paid little attention, for it had been just so with respect to other ailments, and no ill results had followed. I awakened her,[2] but, much to my surprise, she was unable to stir; she could not open her mouth. In vain I tried to stay the trouble, which I supposed to be momentary. . . . She remained in this state three days. During that time we had to feed her like a baby, giving her broth in small spoonfuls, her mouth being three-quarters shut. Little by little the trouble left her.

"Another somnambule, after touching a patient whose blood was doubly corrupt—by syphilitic and by scrofulous virus—lost all her hair a few hours after the mere contact.

"A convulsive hiccough, a cough, a stitch in the side, were transmitted by contact to another sleeper.

"Another, from holding for some time the hand of an idiot, remained stupid for some days."

Here are facts it will be easy to make merry over. Idiocy, it will, perhaps, be said, *is* contagious—for magnetizers! Say what you will,

[1] F. Lebrun, "Transmission des Douleurs d'une Personne à une Autre (*L'Émancipation*, Aug. 4, 1838); Lafontaine, "Mémoires," vol. i., p. 87.

[2] The somnambule should never be awakened till all these symptoms have been done away.—*Du Potet's Note.*

the thing will remain true nevertheless. I have myself observed a like case with respect to another disease, though in a less degree. But I do not wonder at the incredulity these facts may meet with. With shame do I confess that after having read, hardly four years ago, the passage I have quoted from Du Potet, I made a big interrogation point and two big exclamation points on the margin of his book. These I now blot out and go on transcribing:

"Here is what Puységur says about this matter: 'The susceptibility of patients *in crises* for catching (*susceptibilité . . . . de gagner*) readily certain maladies, has many times been demonstrated for me. I have seen magnetic somnambules, in the midst of a swarm of many patients, ask [leave] to quit their place, saying that *their neighbors made them ill;* and others to withdraw precipitately. And often I have had to repair the mischief caused by the approach of certain individuals.'"

I observed lately a similar case. A young person, in good health at the time, produced, simply by her presence, an exceedingly violent paroxysm in an endormed lady. Some weeks later this young person fell gravely ill of typhoid fever, aggravated by an old heart complaint. Was it the influence of this on-coming pathological state that caused the mischief, or was it the girl's own individuality? Anyway, there was no suggestion: the girl had no thought of the disease, and she loved the lady well.

"One day (continues Du Potet) I consulted my somnambule, Vielet, upon the kinds of diseases most readily communicable to somnambules; he had himself twice or thrice had a sad experience in that way. His answer, which he gave in writing, and which I still have, was, that the most dangerous are epilepsy, scurvy, diarrhœa, cold paralysis, sciatic gout, catalepsy, itch, cold humors, and all venereal diseases.

"As for myself, I never have magnetized a consumptive or a patient who, having taken [has been taking] mercury,[1] without experiencing, in the former case, pains in the chest, and without feeling, in the latter, pains in the bones, and particularly in the finger-joints and the wrists.

"While magnetizing a young man who had a luxation of the femur in consequence of a lymphatic deposit in the joint, I was seized, on leaving his house, with very sharp pains in the limb on the same side. Believing this to be personal to me, I at first did not give it much attention; the trouble passed away quickly, but on the next day it was the same. Yet, at entering the patient's house, I was not suffering at all; I could not believe in this singular phenomenon, and wished to make sure of its reality, so for two days I suspended the treatment, and felt nothing. I resumed the treatment, my joint was ailing again, and I began to *drag* the leg. I found a pretext for not attending to the case. *I did not at that time know that in magnetizing*

[1] *Sic* in the original: *un malade qui, ayant pris du mercure.* Instances of similar defective grammatical construction are rather frequent in these quotations from authors, and the translator has for the most part retained them in the English version.

without contact the action is of the same efficacy, and that this inoculation[1] *might have been avoided.*

"One day, while making some experiments upon a young man suffering from a syphilitic malady (of the existence of which I was unaware), I held his knees between mine (according to Deleuze's method). After about a quarter of an hour I felt sharp pains in my legs. I asked the patient to tell me whether he himself had pains in the same region; he answered that just then he did not suffer pain, but that usually his suffering was unbearable. I desisted from my experiments, and the pains I had thus 'caught' persisted for a part of the day.

"In consequence of this discovery I have many a time said to patients that I was magnetizing: You have pain in such a part of your body; and every time this proved to be true.

"Having never had any disease, and never having suffered from pain or ache, when I feel some pain in magnetizing I know it comes not from me, and I hold myself sufficiently aloof from the patient to discontinue the facts of this inoculation.

"Other magnetizers have told me of facts of the same kind. I confess that for a long time I refused to believe their testimony and my own as well. This is no longer possible for me, for I have observed too much to harbor a doubt.

"In order to avoid these mishaps I advise the practitioner to magnetize by touch as seldom as possible."[2]

But the absence of contact is no absolutely sure guaranty. Sometimes, though rarely, transmission takes place at some distance in case there has been established between two persons the close and strange relation which we have not yet explained, known as the "magnetic rapport." Du Potet himself cites some cases of this sort:

"*Inoculation without Contact.*—By a singular play of the magnetic forces, and perhaps because of the analogy of two nervous systems, unexpected phenomena sometimes occur. Thus I have many times seen a rapport set up between magnetized subjects that did not know each other, and what one felt was felt by the other, though often they were separated by walls. This makes a good deal of trouble for you, for while you are giving all your care to the patient that is affected sympathically, the other, whom you have left at rest, becomes agitated again and the paroxysm returns, and *vice versa*. In this way hours pass in useless and very fatiguing work; then the hours have to be changed, or you must find some one to take your place with one of the two patients. Do not think that in these cases imagination plays a part. In a hospital in St. Petersburg[3] where two epileptiform nervous affections were given to me for treatment—complaints that I cured, though they were serious and of long standing—well, though the patients were separated by a great distance, and one was on the first floor, the other on the second, the moment I magnetized the one the other had a crisis, yet there was nothing to convey intelligence to the one I did not magnetize; and not once only, but twenty times,

[1] Transfer of disease to the magnetizer.

[2] Du Potet, "Manuel de l'Étudiant Magnétiseur," pp. 251–256. Paris, 1868.

[3] See *Journal du Magnétisme*, vol. i., p. 289.

both at night and in daytime, have we been able to observe this singular phenomenon. My entry was unannounced, made without any noise whatever; often, indeed, the two patients would be in natural sleep; yet, no matter which one I magnetized first, *the one I was not thinking of at all* soon would come out of her sleep and utter fearful shrieks. I permitted this sympathy to go on for a while, for my own instruction, but then I broke it up by producing several artificial crises in succession. Thus I removed the too acute sensibility of their nervous systems."

There was a simpler way, viz.: *forbidding* the somnambule by verbal suggestion to undergo any involuntary action. This recourse is always successful, provided it be availed of in a state approaching monoideism.

"Here is a fact more incredible still, yet no less true. Magnetism is bound for a long time to come to exercise the mind of the physiologist and the psychologist. Facts novel and incomprehensible are coming into notice every moment, owing to the singular properties of the agent employed. I was attending a patient living in the street *des Mauvaises-Paroles*, in Paris. He was but little sensitive to magnetism. But one evening he experienced pretty violent commotions (*éprouva des commotions assez violentes*). I left him resting quietly. The next evening the same phenomenon; but another patient whom I was attending, and who did not know the first at all, had set out for Fontainebleau a few days before. This man, too, was very little sensitive to magnetism. But what was my astonishment, when after three days he came back to Paris, to learn from him that he had experienced violent jerks (*secousses*) at the same hour, the same minute, and for the same length of time. At the moment I made no remark, but that very evening I magnetized this patient. He lived in the street *Coq-Héron;* the other patient, he of *Mauvaises-Paroles* street, had the same nervous symptoms. I ceased and the nervous affection stopped. I resumed the magnetization *at other hours*, and this singular rapport was broken up. I repeat, these men did not know each other at all, and knew nothing of the curious observation they afforded me in this way."

This last fact is not conclusive. If the change of time sufficed to break up the rapport, then no rapport existed. When a phenomenon, apparently inexplicable, manifests itself at a fixed hour, it is nearly always explainable by imagination, conscious or unconscious. Mr. Du Potet does not say expressly that he magnetized his second patient at the same hour at which he had been in the habit of magnetizing the first, but that seems to have been the case. Now, nothing is more common than the coming-on of a nervous trouble at the habitual time of hypnotization. Anyway, Du Potet's observation is recounted too vaguely to be of any service as proof. I have cited it, therefore, only to show the possibility of facile illusion in similar cases.

The following is an observation of Charpignon's:

"We have had occasion (he writes)[1] to operate in a case of acute arthritic rheumatism on the second day of the attack. It is needless to speak of the sharpness of the pains and their continuance for five or six weeks. A few days of magnetization brought about a gratifying alleviation, and the relief would soon have been complete *had not we ourselves been seized with symptoms of the same disease.* This accident taught us the value of the advice given by magnetizers, *to demagnetize* oneself after having operated in certain maladies. We had to suffer then, as on many another occasion, for this carelessness."

The fact, then, is vouched for by many practitioners; still, we must not exaggerate it. It is rather rare, and depends upon a multitude of conditions that make the studying of it difficult. In the first place, there are magnetizers that never have witnessed it. The person that experiences this contagion from time to time, may not experience it in the case of a very serious malady, but may undergo its action very distinctly indeed in some case of little consequence. It seems that here, as in all instances of contagion, individual predisposition counts for more than the agent itself. And in the present instance this predisposition is itself conditional, depending as it does on a certain *momentary rapport* between the patient and the magnetizer. So to speak, the two must be tuned in one key. Magnetizing by passes facilitates this "tuning," but it seldom attains the degree of concord that brings about communication of pains, more rarely produces transmission of objective sensations, and more rarely still thought-transference.

It is generally thought that contagion is always material. That is an error. There are two kinds of contagion, to wit:

1. *Material contagion*, which might be subdivided, but which is not of interest to us here. Its agents are visible parasites, microbes, virulent liquids, and miasmata. (I should be much embarrassed were I asked what a miasma is, but I suppose it is some deleterious gas.[2])

Barring cases of direct communication of the parasite, or direct introduction of the virus into the blood, this contagion is never inevitable; but non-hypnotizable persons are liable to it in the same degree as the hypnotizable; and if anything makes resistance against it, it is the general state of the individual's strength and health (physiological resistance), without regard to his sensitivity. It manifests itself, however, only in a few categories of diseases known as contagious.

2. *Nervous Contagion.*—This is twofold:

[1] *Op. cit.*, p. 179.

[2] This is not exactly Mr. Béchamp's definition, who says that miasmata are "agents whether ponderable or *imponderable*, diffusible, without definite form, of a *physical* or a chemical nature, which, *transported by the air*, are able to modify at many points at once the functionment of that which is anatomically alive in us, the microzyma."—*Bulletin de l'Acad. de Méd.*, p. 1727. 1884.

a. Psychic nervous contagion (imagination, imitation, ideoplasty), from which very many persons are exempt—some 70 per cent.—but which manifests itself in a larger number of diseases (contagious or non-contagious), but particularly in nervous maladies of the cerebro-spinal and ganglionary systems. It is more widespread than one supposes, but it does not, any more than material contagion, enter into the plan of our present study.

b. Physical nervous contagion (communication nearly always by contact, but almost solely in consequence of a magnetic rapport, so-called). It may apply to different diseases, mostly those not materially contagious, but especially to states of exhaustion, general indisposition and pain, and these usually in a very mild form.

These three kinds of contagion, and the first two in particular, of course, in practice, come together. The third may be considered as comparatively unimportant in everyday practice. Nevertheless, it possesses for us the highest *theoretic* value, since from that point of view it constitutes the basis of sympathism in general, and of mental suggestion in particular.

But, unfortunately, we are still far from understanding this basis, on which rest other phenomena still more recondite. Nevertheless, we must do what we can to obtain some sort of a conception of it.

To this end let us look at the question on the reverse side. If *disease* is transmitted by contagion, *health* should be transmissible in the same way. In truth, both express only a relation: they are not things, only states. Health represents harmony of the functions, these being in equilibrium with the influences of the world without. Disease means the opposite of this: it is dysharmony of the functions, these not sufficiently withstanding the influences of the environment. If this be so, then health must be, so to speak, *more contagious* by bodily contact than is disease, being more expansive, in that it re-acts better outward. Only it must not be forgotten that we are looking at things from the physical, the dynamic standing-point.

Now, taking this point of view, that is what we actually see. Apart from material and psychic nervous contagion, a person that enjoys health and strength gives more of good than a person weak and sickly gives of ill. What they call animal magnetism,[1] so far as it is physical action, is nothing but a contagion of health and of force. And, on the whole, the one that is magnetized gains more than is lost by the one that magnetizes. Here the analogy with the loadstone is perfect, and it is pretty evident in the phenomena of attraction, of specific (*spécifiée*) affinity, and action from a distance.

[1] We shall not dispute about words. The word "electricity" (ἠλεκτρὸν, amber) has no more to do with the batteries and dynamos of to-day than the word "magnetism" with certain physiological actions—rather less. But all words change their meaning with the march of progress, and of this we need not complain.

And if magnetic action in general may be considered as contagion, mental suggestion is contagion also, in a still more striking way.

Bodies when brought together tend to equilibrium of their molecular motions. That is an intelligible law, consistent with all our knowledge, and easily verified in sundry classes of phenomena. Why should organic bodies not come under it, seeing they are far more active, far more expansive centers of force than dead matter? In fact, among these molecular movements produced, that is, transformed within the organism, there are some with respect to which doubt is impossible. Such is heat; electricity also, though less evidently. These two forces, *i.e.*, these two kinds of molecular motion, cannot be circumscribed by any superficies. Heat and electricity are ever escaping at every point, and it were foolish to suppose that though they re-act upon the ambient atmosphere, they shun other organic bodies and are indifferent for them.

Now, animal heat and animal electricity, themselves alone, suffice to account for very many magnetic phenomena. Their weakness, physically, has long deceived us. People have thought that to produce a physiological effect there must be actual fire, or electric batteries contracting the muscles. But the warmth of the hand is much more effective than a blaze, and metalloscopy, the action of the magnet and of very weak electric currents, much more effective than that of strong currents. The more like a remedy is to the normal agencies of the organism, the better it is. And, plainly, nothing more resembles the internal currents that keep up the harmony of the functions than those very currents themselves in a like organism, but one in better equilibrium. On the other hand, we should be surprised were the presence of a living body, *i.e.*, of a complexus of vibrations and currents, to have no influence upon another like complexus. A matter less clear, in the present state of our knowledge, is this specific affinity of certain vibrations of certain organs for those organs only, the transmission from a nerve to a like nerve in another body. But that is chargeable only to our ignorance. Then, in two pianofortes that stand side by side, do not two like strings act in the same way? And when two wires lie side by side and an electric current is passed over one, is not a like current, in the reverse direction, produced in the other by induction, whereas you see nothing of the kind in a rod of wood or of glass? Thus, there is an affinity of nature, and there exists no reason why a nerve that is disordered in its molecular state should not act *by induction* mainly upon a like nerve.

Not to enter upon these questions of elective sympathism of parts, it is plain, as all organic changes may be reduced to changes *plus* or *minus*, that the energy whose intensity is normal, acting upon several associated parts, whereof some have an excess and others a lack of energy, will tend to equalize their tensions—that is, to restore their

equilibrium; and inversely, an association of unequal energies will produce a like break-up of equilibrium in a like association.

"Every living being (says Jussieu, in his interesting report upon mesmerism) is a true electric body, constantly impregnated by this active principle, but not always in the same proportion. Some have more of it, others less. . . . Hence we see why by some it must be given out, and taken in or eagerly imbibed by others; that nearness to the one in which it abounds is of advantage to the one in which it is deficient. The sleeping of a child with an aged person is good for the latter, bad for the former. Plants, when brought together in a seed-plot, are strong and healthy; but in the neighborhood of a large tree they wither and perish."

The latter fact has been confirmed by recent researches, and it is certain that Jussieu judged it aright when he attributed the effects mentioned to absorption of electricity. But what he says of electricity applies equally to *all* molecular motions and to all organic states, though this influence may not be visible save after manifold transformations, due to the influences of the media.

Is the fact of physiological transmission between a child and an aged person empirically ascertained? Hitherto modern science has not concerned itself with these questions; but science in former times looked on the fact as quite natural, and it has a place in popular beliefs. I have heard of many instances of cure, particularly of rheumatic complaints, effected solely by contact with young and healthy persons, or even with young and healthy animals. In one case, too extraordinary to be quoted as evidence, *fowls* served as the remedy, and *they died* after curing the patient! I cite this merely to direct the attention of observers upon a fact of everyday occurrence in rural districts; and physicians are perhaps in the wrong when they treat such stories with contempt. Facts of the kind are found in the history of Hungary. I find the following in Cabanis:

"In general, the emanations of young, vigorous animals are beneficial; consequently they produce agreeable impressions, more or less distinctly noticed. Hence the instinctive attraction whereby we are drawn to them, and which gives us to feel an organic pleasure in seeing them, being near them, even before any thought of a relation of affection or of utility intervenes. The air of stables that contain cows and horses, if they are kept clean, is both agreeable and wholesome; it is even believed—and the opinion is not altogether without foundation—that in certain diseases this air may be employed as a remedy and contribute to the cure. Montaigne tells that a physician of Toulouse, having met him in the house of an aged cacochymic patient whose health he was caring for, being struck with the young man's hearty, vigorous looks (for the philosopher was then hardly twenty years old) bade his patient keep around him persons of that age, whom he deemed to be no less of service in re-animating the old man than in cheering him. The ancients knew how useful it is for languid age and for patients exhausted by the pleasures of love

to live in an atmosphere filled with the restorative emanations given out by bodies young and full of vigor. We see in the third book of Kings[1] that David lay with comely damsels to warm him and to get back a little strength. According to Galen,[2] Greek doctors had long recognized in the treatment of sundry consumptions, the advantage of making the patients take nourishment from the breasts of young, healthy nurses; and experience had taught them that *the effect is not the same when the milk is given after being caught in a vessel.* Cappivaccius saved the heir of a great house in Italy, fallen into marasmus, by making him lie betwixt two vigorous young girls. Forestus tells how a young Pole was cured of marasmus by spending the days and nights with a nurse of twenty years; and the effect of the remedy was so prompt that soon there was reason to fear that the convalescent would again lose his strength with the person that had restored it to him. Finally, to bring this subject to an end, Boerhaave used to tell his disciples of having seen a German prince cured by this means, employed in the same way which had succeeded so well for Cappivaccius."[3]

"There is not a housewife but knows that it is not good for a child to make it sleep with an aged person, though the latter enjoy perfect health. In other times there existed in the mountains of Auvergne a custom that may well be mentioned. When any traveler arrived at an hostelry, feeble, sickly, or benumbed by cold, they asked him whether he wished a warmed or a brasiered bed; naturally his answer would be: 'I want a good warm bed.' When about to get into the bed he would be much surprised to see a chubby, hearty, well-complexioned fellow leave it, enveloped from head to foot in a clean linen shirt.

"The next morning our man would be sure to inquire if it was the custom to give one a bed in which another had slept. 'Sir, you asked that your bed should be warm, and we warmed it for you. If you had wished it brasiered, we would have heated it with a brasier.' 'What difference is there between these two methods?' 'O sir, much difference; the bed warmed by a young, strong, healthy person is far more restorative and strengthening.'"[4]

"When we observe," says Hufeland, "the effect produced by placing newly-killed animals on paralyzed members, and live animals on parts of the body that are suffering pain, it does seem that this therapeutic method ought not to be spurned."[5]

Let us enumerate the facts we have been examining:

1. Transmission of exhaustion, of a nervous fatigue caused by any serious illness or the like. This transmission is rather common, always more or less weakened, often to the advantage of the patient.

[1] Our author quotes the Bible according to the LXX and the Vulgate, wherein I. and II. Samuel are reckoned I. and II. Kings, while I. and II. Kings (as reckoned in the Protestant canon) are III. and IV. Kings.—*Translator.*

[5] Hufeland, "Die Kunst das Menschliche Leben zu Verlängern," p. 7. Jena, 1798.

2. Transmission of health and strength, regulative action of a well equilibrated organism upon another organism that is not well equilibrated. This action is still more common, and takes place sometimes at the expense of the transmitter.

3. Weak transmission of pain and other like symptoms, which enables one to appreciate the state of the patient, sometimes through an exceptional sensibility of touch and smell, sometimes by analogous sympathic sensations in analogous organs.

4. Strong transmission of pain and other pathologic symptoms, communicating an analogous complaint to subjects that are momentarily hyperæsthesic, so as to produce a more or less lasting pathologic state. This transmission is rare, except where there is material or psychic nervous contagion.

CHAPTER III.

TRANSMISSION OF EMOTIVE STATES.

COME we now to the fifth group—*transmission of feelings and emotive states generally.* These kinds of transmission are rather common, but they are seldom produced by simple "influence," in the electro-technic sense of the word. In most cases the ordinary sense-perceptions, those of sight and hearing, aid the direct communication with their automatic inductions, more or less unconscious. We know how easy it is to divine the mental state of a person we know from the expression of his face and the tone of his voice.

As direct transmission alone is what interests us just now, we will examine particularly instances where other influences are more or less thoroughly eliminated.

In the following case the influence of imagination is not excluded, but there is little probability that there was any. "One day," says Lafontaine, the man whose experimental lectures at Manchester suggested to Braid the first thought of his discoveries—

"One day, in magnetizing a friend of mine, Mr. Devienne, a painter, I obtained a result of a kind to show the uncertainty of the existence and communication of the vital fluid. Mr. Devienne was suffering from a headache that prevented him from working, and he suggested that I should remove it. I agreed, but on the condition that he should give me a glass of Bordeaux wine, for I was exhausted and ready to drop from fatigue; I had been magnetizing all the time ever since the morning. He hastened to gratify my wish; I ate a biscuit, drank a glass of wine, and commenced the magnetization. I directed all my action to the brain and the stomach, imposing hands on both organs, and while magnetizing I took a second glass of wine. My patient's eyes were shut and he was unable to open them, but he was not asleep.

After an hour's magnetizing the headache was gone entirely, but my friend's gayety was delightful; he talked incoherently as if he had been drinking. I promptly took him out of the magnetic state, and, to my great astonishment, the effect remained; Mr. Devienne was quite drunk, he could hardly stand. He had taken nothing, and I had drunk only two glasses of wine, of which I felt no effect. My fluid, therefore, had become charged with the spirituous parts contained in the wine, and had transmitted them to the patient, leaving no trace of them in me."

Alongside this narrative I also set an exclamation point some years since. To-day the fact does not seem to me impossible. The case is an interesting one in that the action of the alcohol was transmitted directly without producing any marked effect on the magnetizer.

"Since then (continues Mr. Lafontaine) I have many a time in my own practice and in that of other magnetizers come upon this fact of the transmission of physical sensations. I have also seen transmissions of moral sensations (*sensations morales*); the patient would become downcast or joyous, just as he became a sufferer if the magnetizer was indisposed or preoccupied. It was not even essential that the patients should be endormed to experience these different physical and moral effects, it sufficed if they were powerfully magnetized; nevertheless, it must be understood that these were rare instances, very rare indeed, and they were developed only in the case of exceptional individuals." [1]

I would observe that in the case of Mr. Devienne transmission took place in a state intermediate between sleep and waking. Now, it will be remembered how in the case of Mrs. M., who discerned the moral state[2] of persons around her, this phenomenon manifested itself always at the moment of awaking. Nevertheless, somnambulism being a highly variable, a highly elastic state, the conditions of monoideism may be realized therein momentaneously, and then the same phenomenon may occur.

Baragnon gives a case in all respects like the foregoing, and in which the subject was in perfect somnambulism.

"On leaving the table after a dinner at which I had become a little heated [with wine], I was invited to magnetize a young person who was passing the evening at the same party. I brought about sleep with singular energy of action. This I attributed to my excitement, though that seemed to me to be very slight. I was still more astonished to discover in the magnetized person, when she was in the somnambulic state, the most unmistakable signs of intoxication. No one guessed the cause, as I seemed perfectly sober; but, surprised as

[1] Ch. Lafontaine, "Mémoires d'un Magnétiseur," vol. i., p. 96. Paris, 1866.

[2] I doubt whether "moral state" expresses the meaning of *état moral*. But let the reader attach the same meaning to "moral" in this phrase that it bears in "*moral* courage." The word is used as the antonym of "physical." "Moral state" here means the thoughts, sensations, emotions, etc, present in one's mind at a given moment.—*Translator*.

I was myself, I explained this wonderful effect of transmission, producing intoxication in a delicate woman, who was incomparably more sensitive than a man could be to the effects of spirituous liquor."[1]

Here, then, is another case of involuntary transmission, with apparent amplification due to the sensibility of the subject. But it is probable that in these cases psychic contagion played a certain part; in other words, that the subject thought to herself that she was dealing with an intoxicated man, judging by some symptoms more or less faint, and that in a moment of monoideism this idea was realized in herself by ideoplasty.

"Transmission of sensations (says the same author) extends over the two beings through a general and sympathic harmony. The moral impressions of vexation, anger, joy, will be perceptible to the second party *as physical re-action*, if they affect the first party. This organism, wholly controlled in body and mind, will note *far better than I* who am in control, the slightest differences in opinion of the persons around me with regard to myself and my experiments and to magnetism. Is this so because, receiving one after another all my sensations, she analyzes them better than I could do, in the recollectedness[2] which this demi-separation from matter always procures for her?"

To say nothing of the "separation from matter," which is only a phrase, we can understand why the subject should perceive relatively better, and that for two reasons: first, because the subject is *hyperæsthesic;* and secondly, because the subject is *isolated.* The subject is *hyperæsthesic*, that is to say, an excitant insufficient for the magnetizer may be overpowering to the subject. There is no real amplification in nervous transmission, as there is none in any other sort of transmission; but sometimes there is apparent amplification, as for instance in the case last cited of transmitted intoxication. It is as though we were to transfer a burden that we can bear very easily, to the shoulders of another person who is too weak to bear it. The subject is *isolated*, that is, his mind is not distracted; he perceives better whatever is in rapport with the sphere of his occupation for the moment, and he takes in better than we do the meaning of a tone of voice, of a laugh, of a word that escapes from the lips of one in the company. He need not "analyze" his sensations, it is enough that he is *under the action of associations based on unconscious experience.*

[1] P. Baragnon, "Etude de Magnétisme Animal sous le point de vue d'une exacte Pratique," p. 136. Paris, Toulouse, 1855.

[2] *Recueillement.* Webster gives to the word "recollection" as its fourth meaning a sense very nearly the same as that of the French word, but he marks it "rare." The term comes from the theology of the Mystics and of writers on the "spiritual life," and with them means a state of abstraction of the faculties of the soul from all created things and their concentration upon the objects of religious contemplation.—*Translator.*

Baragnon, I am aware, would object that the subject being isolated cannot hear "strangers."[1] But the phenomenon is a complex one. The subject hears only his magnetizer, that is to say, answers the questions of his magnetizer only, and it may be said that he does not really hear, in the proper sense of the word. But it is a mistake to suppose that extrane auditory sensations are totally inactive. *They enter the brain*, and then results a phenomenon that I may call *latent hearing ;* impressions entering thus (I do not say *perceived*) form associations as all other impressions do, combine together, and give resultants that may at a given moment make their appearance amid other and more intense states.

If lucidity (I do not say clairvoyance, but lucidity as the faculty of reflecting),[2] the lucidity that belongs to active somnambulism, must be regarded as unconscious because of the total forgetfulness on awaking,[3] then the latent sensations that are not perceived in somnambulism, but which enter the brain and there produce an action in all respects resembling the habitual actions, though unaccompanied by reflex acts ; these actions, I say, must be regarded as *a second grade of unconsciousness.* Below consciousness are even *several strata of unconsciousness.*

This is proved by a long series of facts, and I go so far even as to say that hypnotic phenomena in general would be more or less incomprehensible without this graduation of the intelligence. Let it for the time being suffice that we derive from these reflections a practical lesson, to wit :

Whoever would experiment to any purpose *must always consider the endormed subject—even in the state of profound aideia, and despite all ordinary evidences of total deafness or blindness—as though awake.*

And "beware of suggestion!" This counsel of Mr. Bernheim ought to be writ in big letters on the walls of all hypnotic laboratories. Mr. Bernheim, however, does not believe—at least did not yet believe in *mental* suggestion when he wrote his treatise. Scientific hypnotizers little think that when they experiment on a highly sensitive subject they inculcate into him their theories, their knowledge (*connaissances*), their fears, even their guesses, and that thus they are tricking themselves while they think they are making discoveries.

[1] For the somnambule *strangers* are all persons with whom he is not "in rapport." In this translation the word *extrane* will be used to express the French adjective *étranger*, as a technical term in magnetism.—*Translator.*

[2] *Réfléchir.* This ambiguous word seems to be used here in the sense of "giving back" (after the manner of a mirror); not in the sense of "considering," "pondering."—*Translator.*

[3] We have no other criterion for determining whether a thought or an action was unconscious or not, save *the possibility of recollecting a few minutes after.* It is vain to look for any other.

Phenomena are summoned as the exorcists of Loudun summoned the devil. So, then, beware also of mental suggestion!

Mr. Baragnon, who was an excellent practitioner and often a very clear-sighted observer, himself points out certain illusions of this kind, and we will quote his remarks presently, when we treat of transmission in detail.

A state very favorable to transmission of feelings and emotions is also easily produced in the hypotaxic phase—that is, in the state which results from passive concentration of the attention before hypnosis, properly so-called, makes it appearance. So this, too, is a state intermediate between sleep and waking. It is often brought about in persons who, while holding their hands upon a table, wait patiently for it to begin tipping. Again, people amuse themselves in company by putting to the "spirit" (*i. e.*, to the medium's unconscious) questions touching the psychic state of those who are present, and thus are discovered not only the good or bad humor, the fears, the cares, the trustfulness or the incredulity of those who are in the company, but also their inclinations, their sympathies, their antipathies.

This phenomenon was very common in the possessed and the demoniacs of past times, and of course was then explained by the intervention of the devil. Here are some instances from the history of the nervous epidemic of the Shakers (*Trembleurs*) of the Cévennes —an epidemic that broke out among the Protestant fanatics in that mountain region of France after the revocation of the Edict of Nantes.

a. "Two boys in ecstasy discerned down to the smallest circumstances what John Cavelier had in his mind. It was just these facts that won him for the revolutionary cause, and, as we know, John Cavelier became thereafter the principal leader of the Shakers.

b. "A crisiac[1] discovers that a man present in the assembly has betrayed them for a sum of money. He goes straight to the culprit and indicates that he has poison hid in the sleeve of his jacket. All this proved to be true; 'I was there,' adds the person who tells the story, 'and I saw it all.'

c. "Another crisiac discovers in the midst of a meeting of 400 or 500 Protestants, two spies, who confess their crime. His name was Clary, and to prove the truth of what he had said, he offered to go through the ordeal of fire, and in fact did. Thus he gave proof of *insensibility* after giving proof of *hyperæsthesia.*"[2]

"As for the Convulsionaries of Saint-Médard (victims of another nervous epidemic appearing about the year 1770, among the Jansenists, at the grave of Deacon Pâris), this is what is said of them by Mr. Poncet, one of the ablest writers on their side (Poncet was so moderate in his assertions that even his opponents said he wrote *pro* and *contra* the Convulsionaries): 'You would have much less difficulty,'

[1] *Crisiaque* (from *crisis*), one that is in the magnetic or hypnotic crisis, or in somnambulism, etc.

[2] "Théâtre Sacré des Cévennes," pp. 38, 45.

he says, in replying to the author of 'Nouvelles Observations,' 'had you witnessed the facts; if being in the company of a Convulsionary, he had told you the most secret thoughts of your heart; if he had warned you against some serious mis-step and you had taken it; if he had pointed out to you just the moment for electing the better part, and you had preferred a less suitable course: if this thing and other things equally well defined in detail, had happened to yourself, you would have been upset and could not have refrained from acknowledging that such warning came from God.' The author of 'Lettres d'un Ecclésiastique de Province,' whose work bears the unquestionable stamp of truth, also declares that 'there are innumerable instances of Convulsionaries discovering in fullest detail the secrets of hearts.' In a writing entitled 'Coups d'œil sur les Convulsionnaires' (p. 8), we read that in many crisiacs the supernatural and the divine are manifested by indubitable signs; among these signs is *manifestation again and again of the secret conscience.* So we find in the heart of Paris, among cultivated theologians, 30 years after the scenes in the Cévennes, the selfsame marvels that had before been attested by uneducated peasants; and these Jansenist theologians assuredly did not seek to liken themselves to persons possessed, or to Protestants, heretics."[1]

In the facts just cited, transmission of thoughts is blended with transmission of feelings; the latter is by far the more common.

A case similarly complicated was observed by Charpignon. He was attending a married lady and encountered sundry remarkable phenomena:

"The lady's husband, at first unbelieving, took so to heart the extraordinary phenomena he witnessed that he became morose. He now thought only about the great questions of man's destiny, and evidently having a tendency to melancholia, he fell into a state of profound excitation, and even thought of blowing out his brains, the more quickly to attain full knowledge of things. He had sense enough, however, to conceal from his wife and family the thoughts that possessed him; he even retired to another apartment.

"All this time the thoughts of the somnambule reflected the mental troubles of her husband. Excitation followed depression, and she suddenly exclaimed, 'Yes, if I had a pistol I'd blow my brains out!' The husband having entered on hearing the cries of distress, 'Listen,' said the somnambule to him; 'you must live, and you have been cowardly enough to wish to die.'" The author adds the following reflections: "Serious worry or deep grief may have the same disastrous results as a disease. The patient feels the sufferings of the magnetizer with all the more pain *as he knows not to whom to attribute* the frightful overturning that oppresses him."[2]

It is to be remarked that in this case it was not the magnetizer, but a third person, that was the cause of the trouble—a third person united

[1] Bertrand, "Du Magnétisme Animal," p. 436.

[2] *Le bouleversement affreux qui l'opprime.* Dr. Ochorowicz gives no foot-note reference to show where the passage is to be found; and though the whole is enclosed between quotation marks by him, some of the remarks, for instance, "The author adds the following reflections," would seem to be his own — *Translator.*

only to the somnambule by the ties of sympathy and of life-association. On this point Deleuze says:

"The action of one individual's thought upon another is still an inexplicable phenomenon, but our thoughts are communicated by speech and by gesture—that is, by sound and light. How know we but that the modifications of our soul may be made sensible by other means? Whence the feeling inherent in human nature, that makes us wish that an absent friend shall think of us? Magnetism gives to this wish a new motive; even explains to us how he who is thinking of another and for his good, acts upon him; and how, rapport once set up, *whether by affections and habitudes, or by physical means*, there may exist communication between two beings that are compelled to live apart from each other. And again, must we not seek in a like principle for the origin of the opinion diffused through all peoples, that wishes have an influence on the health, the well-being of those who are the objects of them; as also for the origin of the opinion so dear to sensitive souls, which leads children to desire and to receive their father's blessing? I do not want to urge these thoughts too far; I hold that though they please the imagination and the heart, and though they account for many of our inclinations, they are not sufficiently proven to be proposed to the reason. I will simply remark that philosophy would gain a good deal could we reduce under natural and physical laws, facts that have the appearance of the marvelous, and which, nevertheless, are attested by enlightened men. It is not the belief in these facts, but the consequences we draw from them, that are the cause of superstition. Say what you will, you never will persuade those who are convinced of the reality of these phenomena, whether by experience or by trustworthy testimony, that they are dupes of an illusion. Compel them to keep silence for fear of ridicule, and they will be none the less ready to attribute these things to a supernatural cause; they will then look on the principles of the sciences and on those who measure everything by those principles, as a system and as men who see only the rind of things. Better were it to bring all the wonder phenomena within the physical order, and to distinguish clearly what truth they may contain from what is actually inadmissible."[1]

These very just remarks may well give matter for reflection to those who understand one thing only—the inviolability of accepted truths. As for Deleuze's suppositions with regard to popular opinions, they are equally just in principle.

I venture to go further, and to say that the human mind is too little inventive to originate any prejudice[2] whatever, with no empiric basis. The question simply is, where does the basis end and where is the beginning of the complementary imagination and of the errors that come from our forgetting the origin of it all? But as for the practical importance of these real facts, it can by no means satisfy the

[1] Deleuze, "Histoire Critique," etc., vol. ii., p. 327. Paris, 1813.

[2] The word is used here in its etymological sense—a *judgment* formed *before* knowledge is had. *Præjudicium*—forejudgment. Just above I have rendered *préjugés*, "popular opinions."—*Translator.*

aspirations of "sensitive souls." The facts of unconscious communication, which may be frequent enough, are quite lost in the torrent of normal impressions and associations; and the facts of definite, experimental communication are so rare that they cannot have any practical value till we shall discover *all the precise conditions* of their physiological manifestation.

But we return to the facts. One must never be troubled about applications when there is question of a new theoretic truth. Let us accumulate facts in order to frame a sound theory; the application will come of itself. Meanwhile this truth embarrasses us sometimes.

"It has happened often to me (writes the Count de Maricourt) to be flustered and embarrassed by the clairvoyance of somnambules in perceiving impressions or divining feelings that I should have wished hidden from them."

I do not question the fact, but the adverb "often" is perhaps too strong in this passage.

I might quote several facts of the same kind; but because of their personal and complicated character it were difficult to tell the tale without entering upon many explanatory details that would overload our study and perhaps add nothing that would be convincing to the unbeliever.

This sort of facts one must observe for himself and keep for his own instruction. It is not to be supposed that a "clairvoyant" somnambule is all the time discovering or reproducing your sensations. In the first place, the somnambules that discover them are rare, and they cannot do this thing every day. As with all transmission phenomena, there are moments—quarter hours at most—during which transmission takes place.

This is true particularly of clear, experimental transmissions and of *detailed sensations*. We are already familiar with some of these facts, as observed in Mrs. M. and Mrs. B. Let us now look at observations made by other experimenters. We begin with some remarks from Baragnon:

"Before devoting oneself to the study of the moral and mysterious union that is formed by the nerve-fluid between two beings, it is well to apply oneself to the observation of facts which disclose a no less abnormal and miraculous closeness of relation (*intimité*) between two bodies.

"Profoundly attached to the physical facts, because I believe it is they that will save magnetism from the destruction that time works, till the minds of men are opened to it [Baragnon wrote in 1853], I see in the fact of the transmission of sensation a new lever against resistance.

"What is this intimate communion of two natures so that the slightest pains, the most diverse physical impressions, being felt by the one are echoed by the other . . . by the other, whose senses are in

abeyance, whose means of perception are effaced? [This effacement is only relative.] We cannot explain such facts; they are found to exist, and that is all. If the magnetizer feels an impression, that instant the somnambule feels a like commotion. If, for instance, you prick the operator's arm so as to cause him pain, the subject will show signs of pain, and will always tell correctly the part that was hurt, whether by burning, or by pricking, or by a blow.

"If the magnetizer is sufficiently stoical to withstand every painful impression, the subject feels nothing or next to nothing. So, as regards smell and taste. If I find the odor of ammonia, ether, or any other smell, the endormed person will name the odor, for he, in fact, will sense it too. Still, this is a fact that must not be confounded with thought-transference."

That is a just remark. There are subjects that take the sensations of the operator without being influenced by his thoughts, and inversely; and with the same subject one of the two phenomena may show itself without the other. Sensations are generally transmitted in a monoideic state, in which *imitation of movements* exists also, while transmission of thoughts seems to require a monoideism a little more passive and, at the same time, a little more absorbed; it is, perhaps, a little nearer than the other to polyideism, while the state that favors will-transmission seems more passive still and nigher to aideism.

The same author makes another just remark with regard to mental influence during experiments in general:

"Let us say upon this point, that if we are trying tests of insensibility upon the magnetized person, and while we are making burns (*opérons brûlures*), suppose we feel some impression of what we are doing—a feeling of repugnance and dislike for committing such *cruelties*—the patient, in virtue of the transmission of sensation, will shudder, too, not from pain, for there is none, but because of the sentiment of pain in us. From this one can judge whether our advice, so often repeated, to keep calm and cool, is of much importance. The re-action of the magnetizer on the subject, in these conditions, is the prime source of the cure, as in the opposite state it is the mainspring of the disturbing principle" (p. 134).

A very just remark. At the time (1845) a sharp controversy was proceeding in journals devoted to magnetism, upon experiments in insensibility, in particular between Mr. Lafontaine, who gave public exhibitions of such experiments, and Mr. Brice de Beauregard, who held them to be infamous, among other reasons, because of the suffering endured by the somnambules at awaking or afterward. Till lately I have been unable to understand this polemic. I have many a time experimented upon the insensibility of somnambules; on many persons I have, with their permission, inflicted all manner of seeming tortures—punctures, burning with melted wax, etc. With punctures, even deep punctures, I have never had the least mishap; in two cases of burning, where a surface of several square centimeters was

involved, melted wax being used in one, red-hot iron in the other, the process of inflammation took the usual course, but without any suffering at all either during the sleep or after. Hence it was with great astonishment I learned that some magnetizers find their patients suffering more or less pain after awaking. Now I know why. After my first experiment, which succeeded perfectly, I felt fully assured that the subject could not suffer at all, and this assurance I suggested effectively to my subjects; whereas operators who have begun with a mishap always thereafter have a fear, an emotion, an uneasiness, a needless compassion, which influence their subjects. Nay, more; the most humane man of all magnetizers, the man morally most susceptible, namely, Deleuze, *never could produce insensibility;* and yet, according to Esdaile, Baragnon, Lafontaine, Du Potet, and others, anæsthesia is one of the most constant characters of nervous sleep! Deleuze, after quoting several cases of insensibility vouched for by physicians, says:

"*My somnambules never presented it;* their sensibility was, on the contrary, *more delicate* than in the waking state; the contact of a body not magnetized was disagreeable to them, and the touch of an extrane person gave them much annoyance. *I even know for certain of patients falling into convulsions and awaking because of being touched suddenly by someone not in rapport.*"[1]

All this is true, but the opposite side is in the right also.

One produces insensibility when one is sure that it will be produced. And so with respect to all other phenomena, symptoms, states—account, of course, being made of the subject's hypnotic sensibility.

"One day," says Perronet, "I fancied that a subject was fatigued and that the attitudes taken by him, counter to the laws of gravity, must exhaust his muscular strength. Straightway, at the very instant of this reflection—an erroneous one, no doubt—I saw his limbs relax and become inert and flabby; when raised and let go, they fell like lifeless masses, or like the arms and legs of Policinello. . . . After four or five minutes, in a moment of ill humor, I had a strong will to revive in the subject the properties belonging to the cataleptic state; and I had the satisfaction of succeeding. From this experience I concluded that in the phenomena of catalepsy all depends on volitive or intuitive direction on the part of the operator, regard, however, being had to the subjective predisposition of the catalepsied subject."[2]

It may be remarked that Mesmer, a man of nervous, irascible temperament, and who despised somnambulism, seldom produced it, while he nearly always produced the convulsive *crises*, which he regarded as necessary; that Puységur, calm and of a kindly disposition, rarely produced spasms, and nearly always somnambulism; that the forceful Lafontaine produced profound and lasting states; that if the

[1] Deleuze, "Instr. Pratique," p. 139.

[2] Perronet, "Du Magnétisme Animal," p. 15. Paris, 1884.

credulous Billot did but obey the spontaneous divagations of his somnambules, Donato, full of self-confidence, controls them like trained animals; that if many magnetizers recommend the deepest stillness, so as not to delay the coming on of the sleep, the priest Faria and General Noizet brought it on by shouting "Sleep!"; that if some magnetizers fail to produce suggestions, the Nancy school acts solely by suggestion; that if the regulation three states[1] exhibit themselves daily at the Salpêtrière, that happens rarely elsewhere; that "the cause that makes, unmakes," rarely, however, anywhere save at the Pitié.

It is as with new remedies, which act efficaciously only while they are the fashion—"Hurry up, for it is curing folks now!"

But, then, is it all illusion, and does it all depend on the sensations, feelings, beliefs of the operators?

No; there is truth in all these conflicting observations; only one must not generalize too much; we must not give way to a first impression, or work ourselves into an enthusiasm for an impossible idea, for an observation that perhaps has no better foundation than chance or peculiar circumstances.

One needs to preserve in the current of research *neutrality of feeling*, for all your rather bold guesses have an echo in the highly sensitive subject, and they lead you astray. Do not forget that you are not dealing with a comet, which does not trouble itself about your telescope, nor with a chemic combination, which, while undergoing the action of your reagents, is concerned no further with them.

What would be thought of a physicist who, wishing to make a nice galvanometric test, should load his pockets with chunks of iron or with magnets?

Let us go back now to our sheep. Here is an observation of Mr. Peter Janet:

"Mrs. B. seems to feel most of the sensations felt by the person that has endormed her. She believed she herself was drinking when that person drank. She always knew exactly the substance I put in my mouth, and distinguished perfectly whether I was tasting of salt, or pepper, or sugar."[2]

And in his last note[3] he adds the following:

"We have noticed that the phenomenon keeps on, even though I be in another room. . . . If, even in another chamber, I pinch myself strongly on the arm or the leg, she cries out and is angry because she, too, is pinched on the arm or on the calf. Finally, my brother, who was present at the experiments, and who had a peculiar influence over her, for she confounded him with me, tried a curious experiment. Going into another room, he made a severe burn on his

[3] *Revue Philosophique*, No. 8, Aug., 1886.

arm, Mrs. B. being at the time in that state of *lethargic somnambulism*[1] in which she takes mental suggestions. Mrs. B. was crying out wildly, and I had difficulty in restraining her. She had hold of her right arm above the wrist, and complained of suffering greatly there. Now, I did not myself know exactly the spot at which my brother had intended to make the burn. *It was at that part.* When Mrs. B. was awakened, I noticed with astonishment that she still held her right wrist and complained of suffering greatly therein, though she knew not why. *The next day she was still treating her arm with cold-water compresses,* and in the evening I found a swelling and a redness, both very apparent, at the exact place on which my brother had made the burn on his arm; but it must be remarked that during the day she had touched and rubbed the arm. . . . This phenomenon of communication of sensations appeared only after a long series of seances and at the end of one that lasted several hours; therefore I have never seen it again presented with the same definiteness."

I was not present at this experiment, but I saw the burn on Mr. J. Janet's arm—a large burn and one that must have been very painful. Similar facts have long been observed by magnetizers, for example:

"The phenomenon of transmission of sensations from the magnetizer to the magnetized (says Lafontaine) was one day manifested at Clarisse's. I then went down to the floor below with two persons, who inflicted a thousand little tortures on me—pulling my hair, tickling, pricking, and so-forth. When we went upstairs again, we were told that the somnambule had indicated all these sufferings in the order in which they had been inflicted on me. *This is one of the phenomena I have seldomest come across.*"[2]

Among recent experiments are to be mentioned those made by the London Society for Psychical Research, which has done so much to advance the study of these delicate questions of psychology, hitherto entirely neglected:

"*Community of Sensations.*—We come now to a question much debated and very open to discussion. We hold—and here we have the support of the previous experimenters—that we have often observed a truly remarkable *community of sensations* between the operator and his subject—a phenomenon that perhaps might more correctly be called transmission of sensations. This phenomenon is nearly allied to those with which the committee on thought-transference is concerned. But our experiments differ from those made by the latter committee in this, that the subject is not in his normal state, but is in the 'mesmeric sleep.' The experiments were conducted as follows: Frederic Wells (the somnambule, a young man of twenty years) sat in a chair with his eyes bandaged, and Mr. Smith stood behind him. The subject was put to sleep by Mr. Smith by the use of passes. Mr. Smith was then pricked or pinched pretty hard on different parts of the body, this operation lasting generally a

[1] "Lethargic somnambulism" is a contradiction. The state in question was one intermediate between aideia (lethargy) and polyideia (somnambulism), in other words a monoideic state.—*Note by Dr. Ochorowicz.*

[2] Lafontaine, "Mémoires," vol. i., p. 157.

minute or two. Absolute silence was observed, barring the necessary question, 'Do you feel anything?' This question was pronounced by Mr. Smith, for the subject seemed not to hear the other persons. In the first set of experiments Mr. Smith held one of the subject's hands, but that precaution having afterward been found useless, all contact between operator and subject was broken off in the subsequent experiments."

First series, January 4, 1883:

1. The upper part of Mr. Smith's right arm was pinched several times. About two minutes after, Mr. Wells began to rub the corresponding part of his body.
2. Back of neck pinched. Same result.
3. A blow on the calf of left leg. Same result.
4. Lobe of left ear pinched. Same result.
5. Back of left hand pinched. Same result.
6. A blow on the upper part of the back. Same result.
7. Hair pulled. Wells locates the pain in his left arm.
8. A blow on the right shoulder. The corresponding part indicated exactly.
9. Back of left hand pricked. Same result.
10. Back of neck pricked. Same result.
11. Left great toe squeezed. No action.
12. Left ear pricked. Corresponding part indicated exactly.
13. Back of left shoulder struck. Same result.
14. Calf of right leg pinched. Wells touches his arm.
15. Palm of left hand pricked. Corresponding part indicated exactly.
16. Neck below right ear pricked. Same result.

Thus we find in 16 experiments 13 successes and 3 failures.

In the second series of experiments, Wells's eyes were bandaged as before; but, furthermore, there was a screen between him and Mr. Smith. For a while during the experiments Mr. Smith was in a neighboring room, separated from his subject by a thick curtain.

Second series, April 10, 1883:

17. Upper portion of Mr. Smith's left ear pinched. After about two minutes Wells exclaimed: "Who is pinching me?" and began to rub the corresponding part.
18. Upper portion of left arm pinched. Wells indicates the spot almost immediately.
19. Right ear pinched. After about one minute Wells struck his own right ear, as though brushing away a fly, exclaiming, "Won't you leave me alone?"
20. Chin pinched. Wells indicated the place almost immediately.
21. Hair pulled. No action.
22. Back of neck pinched. Wells pinched the corresponding part soon after.
23. Left ear pinched. Same result.
24. Salt put in Mr. Smith's mouth. Wells exclaimed: "I don't like to eat wax candles"—an idea no doubt suggested to him by the words "wax candles" uttered in his hearing a few minutes previously.

25. Some ground ginger given Mr. Smith. "I don't like things that burn. Why do you give me pepper that way?"

26. Some salt. "What disgusting stuff is this?"

27. Some wormwood. "You hurt my eyes; I do not like mustard."

(It is to be remarked that in the last two experiments the taste of the ginger continues, and is confounded with the new sensations.)

28. The calf of the right leg pinched. Wells becomes angry and refuses to speak. At last he stretches forth the right leg violently and rubs the calf.

After this experiment Wells becomes quite angry and will no longer answer any questions, saying that were he to answer people would keep on pinching him. (During this time the calf of Mr. Smith's left leg was continually pinched.)

Thus in twenty-four experiments on touch there were twenty successes. Of the four checks two might have been foreseen, for transference is seldom produced by pulling the hair. Once the response was not given, and once only was it false.

The report is signed by Messrs. W. F. Barrett, Edmond Gurney, Frederic W. H. Myers, Henry N. Ridley, W. H. Stone, George Wyld and Frank Podmore.[1]

To this report it might be objected that for a good deal of the time the co-operation of the hearing of the subject was not excluded. But that objection cannot weaken the general impression made by the experiment; that is fairly conclusive. Besides, other series of experiments were made for three years, and always gave similar results.

But how is it possible for the pain of the operator not only to be felt by the subject, but even to be *localized* so exactly? However extraordinary this may seem, it is not, I believe, unintelligible.

If, in order that the transference may take place at all, there must be a sort of *regulating;* if the *tonic movement* of the subject's organism has to be brought into accord with the tonic movement proper to the organism of the operator—this by means of repeated touching, passes, etc.—the special regulating of the corresponding nerves is given in advance. We may suppose that there are differences among the several parts of the organ of touch, and that one part, a, accords better with a corresponding part, a', of another organism than with the parts b', c', etc. We do not know wherein this difference consists—it may be very complex—but suppose there exists in the analogous part only one analogous character: that of a determinate *resistance* for certain currents. Now, there are found among physical phenomena dependences of this kind.

Remember, first, that, as here in *physiological sympathism*, so in *physical sympathism*, direct contact is not necessary. A magnet will magnetize from a distance a piece of steel, without producing any

[1] "Proceedings of the Soc. for Psych. Res.," vol. i., part 3., July, 1883.

perceptible action on other metals. Soft iron, too, is magnetized, but only for the moment. We might say that if we liken the magnetizer to a magnet, somnambules that feel his action slightly are comparable to iron, while those that are affected by it for a certain time may be compared to steel. We know that if a magnet undergoes a change in its molecular energy, its armature, at a greater or less distance, feels the change in the same degree.

Then, it is known that as there are electrostatic machines that produce electricity by direct friction, so there are others that charge themselves and produce electricity "by influence"—*i. e.*, without contact. The comparison is not entirely exact. But substitute galvanism in place of electricity. In galvanism not only is contact not necessary, but no poor conductor can prevent the phenomena of *induction*—that is, of *physical sympathism*. A wire insulated as thoroughly as possible, and even at some distance from another wire, will produce in the latter a corresponding current so soon as it is itself traversed by a current. So inevitable is this phenomenon that it forms the principal obstacle to telephonic communication. If upon the same poles are suspended telegraph wires, though a meter or more distant, there will be heard strokes (*coups*) in the telephone at each interruption of the telegraphic current; and even telephonic currents themselves alone, when brought together on many wires in a central station, get mixed by induction.

Suppose, now, that the wires, instead of being stretched in a right line, are coiled as though wound on a bobbin. A bobbin having a certain number of coils presents greater or less resistance.

The bobbin constitutes the essential part of a telephone. Take a telephone circuit, longer or shorter, uniting two stations. At each station are two telephones interposed in the circuit, but while the bobbin of telephone *a* has a resistance of 300 ohms, that of telephone *b* has only 3; so, too, telephone *a'* has high resistance, and telephone *b'* very low resistance. You employ as transmitter telephone *a*, into which you speak; your words will be transmitted, and you will be heard distinctly at the other station, *but only through receiver a'*—receiver *b'* will be mute or nearly so, according to the degree of difference in quality of the wire, the number of coils, etc. So, too, if the answer is given through *a'* you will hear only through *a*.

And yet all four telephones are on the line.

They may also not be in contact; the bobbins may be simply placed side by side, and you will obtain *by induction* the same result.

I do not mean to force the analogy, which is but partial.

The phenomenon is always comparatively much more simple in a complex of bobbins than in an aggregation of cells.

The currents in the organism may not be all alike. They may even present a great number of differences as regards their nature, velocity,

amplitude, intermittence, etc. But it is none the less comprehensible that the excitation of a certain determinate *modus* will be more easily echoed, and chiefly by an organ susceptible of like vibrations.

Not to enter into details concerning these nerve-vibrations, of which we are ignorant, we may state the question thus:

Are there electric currents in the nerves? Yes! Have the electric currents the property of self-induction at a distance despite all sorts of obstacles? Yes! Is this induction always palpable? No! For that purpose we require instruments of extreme sensibility: to wit, good subjects. Is there a constant relation between excitations of nerves and the electric currents of those nerves? Yes!

Well, it is enough that a given excitation of nerve A, accompanied by electric change *a*, produce by induction a like change *a'* in a distant nerve A', to make that nerve reproduce the given excitation, in virtue of the principle of *inter-organic* associations mentioned above.

Nor is it contrary to reason to hold that this transmission, or this induction, may also be direct, that is, even without the intervention of electric currents; the nerve-currents may equally induce themselves.

Hence, there is no need of supposing a new force to make these phenomena comprehensible; we have only to broaden and to subtilize a little the properties of known forces and the laws of re-action, which are probably inherent in all natural motions.

Finally, we must not forget that precise localization is very rare. There are subjects that distinctly feel the pain in a corresponding organ, *but not on the same side.* It seems that in that case induction acts on the more sensitive side, or on the *nodi minoris resistentiæ.*

CHAPTER IV.

TRANSMISSION OF IDEAS.

WITH the transference of sensations we quit the region of sympathic localization. *Ideas* are not localized.

Here, of course, as everywhere, there are degrees.

Sensations of sight and hearing have less local relation with their organs than have sensations of touch, but they are so akin to ideas properly so-called that there is no use in treating them separately. If I transmit the sense-image of the king of diamonds while gazing at it or simply imagining it, there will be only a difference in the degree of clearness of the representation, whereas in tactile sensations, which we have been considering, the *emotional element* made a marked difference.

In the sphere of ideas, therefore, we shall look for a more subtile action, and we may expect that direct, clear transmission will be still rarer there.

The reader will recall the experiments made with Mrs. D. (p. 51, *seq.*, *supra*), but it is to the English Society for Psychical Research in particular that the honor belongs of having conducted a great number of studies of this kind, made with remarkable precision and perseverance. These must be regarded not only as the starting-point in the study of mental suggestion, but in general as a new impulsion given to psychological science as a whole. There is no doubt that they mark a new era in modern psychology.

In sundry of my works in the Polish language, and particularly in a study upon the actual state of psychology, published in 1881 in Mr. Ribot's *Revue Philosophique*,[1] I showed the absolute necessity of *collective work* in psychology. The English Society was the first to undertake it, and we see what enormous strides we have made in these last years!

The results of the English Psychical Research Society upon mental suggestion are contained in four reports of a special committee, on which were Messrs. Edmond Gurney, F. W. H. Myers, F. Podmore, and W. F. Barrett, Professor of Physics in the Royal College of Science for Ireland. Experiments have also been made by Mr. Henry Sidgwick and Professor Balfour Stewart. They were carried on at Buxton, Cambridge, Dublin, Liverpool, etc. Everywhere the result was the same: verification of the existence of the phenomenon. The following table shows the ratio of successes in the early series:

WITH MENTAL SUGGESTION.		WITHOUT MENTAL SUGGESTION.	
1 success in	1½ exp.	1 success in	52 exp.
1 "	3¾ "	1 "	90 "
1 "	13 "	1 "	52 "
1 "	12½ "	1 "	90 "
1 "	10 "	1 "	52 "
1 "	3½ "	1 "	12 "
1 "	2 "	1 "	4 "
Mean	1 in 6½	Mean	1 in 46

The experiments were made with playing-cards, objects of different kinds, names, and numbers. But the most interesting results were obtained with drawings. In volume i., part 3, is given a series of demonstrative tables.

My experiments with drawings have been much less striking, and I believe that in this and in other respects there are great individual differences, particularly between subjects, but also between operators.

[1] "Projet d'un Congrès International de Psychologie." (*Rev. Phil.*, vol. xii., pp. 1–17, 1881.)

For example, I have observed, I think, that an almost hallucinational image is transmitted better than an image really seen, despite the greater apparent distinctness in the latter case. But it is certain that an hallucinational mental image is more *monoideic* than an image merely seen. There are also differences with regard to the subject; some subjects are influenced most by visual images, others by mental sounds, others by motor images.[1] Transmission would seem to be appreciably helped when two persons that are able strongly to concentrate their thoughts act together, and when one thinks with the aid of visual images and the other with the aid of the sounds of the same images mentally produced.

But one fact specially worthy of attention, and one positive result of my experiments, is, that successes come by series—that is to say, there are fluctuations in the state of the subject which either help or hinder transmission. These series are perhaps more constant in somnambulism than in the waking state, but the principle of sympathic impressibility is ever the same. If there is to be transmission the brain ought not to be too torpid (aideia), nor too distracted (polyideia), nor too absorbed in its own thoughts (active monoideia); it ought, on the contrary, to be passive, *but capable of functioning with absorption* (passive nascent monoideia). The nearer the momentary state comes to this limit the better is the chance of successful transmission

But besides immediate transmission there is *latent* transmission, and *retarded* transmission. The subject's state may not permit direct communication (on account of the pressure of the thoughts that occupy him, or because of the torpor of the brain), but communication is effected all the same insensibly, and the idea taken in unawares makes its appearance unexpectedly in a subsequent experiment, or apart from experiments. Mr. Richet makes the highly important observation, that transmission is made more easily from the conscious to the unconscious than between two conscious states. Is it easier still between two unconscious states? We are unable at the moment to decide the question. It may be that the transmissor state must be the stronger, and usually (not always) the conscious states are the stronger; but perhaps also between two unconscious states, despite their habitual weakness, *mutual sympathic adjustment* is easier.

[1] Perhaps the reader will have some difficulty in understanding the terms, visual images, mental sounds, and motor images. Their meanings can be readily seen from an illustration: A sees a piece of piano music, knowing nothing at all about musical notation. The impression on his sensorium or brain is a purely *visual* image. B sees the same piece, but he can "read" music, and can imagine how it sounds when played on the piano; that imagination is *mental sound.* C also reads music, and in particular is a performer on the piano: as he reads he imagines himself playing the piece—*i. e., putting in action* the muscles concerned in performing on the piano. The piece of music impresses *motor* images on C's sensorium.—*Translator.*

However that may be, the best conditions for such transmissions as we know of are these:

On the part of the operator, the state of definite (*déclaré*) active monoideism;

On the part of the subject, the state of passive nascent monoideism.

The first is akin to polyideism, the second to aideia.

Consequently, the receiver-subject is not to reflect nor to divine, but to *undergo*, the action of the thought transmitted. It may be said almost without hesitation that this transmission—even when it takes place in a conscious state—is always effected by the unconscious strata of the mind as an intermediary. Hence it is that the subject can but seldom tell whence the transmitted thought comes to him, and he inclines to consider it as a spontaneous act of his own mind rather than as a suggestion from others. Two or even many thoughts may be transmitted simultaneously by two or more transmitters, but then they are still more subject to the influence of the individual medium[1] that receives them, and generally combine to produce a resultant, a *complexus* modified and accommodated to the associations personal to the subject.

It is probable that most of the transmissions that take place in ordinary life are always unconscious, though made manifest in their effects. They *partly* account for the undoubted phenomenon of the history of civilization, that certain ideas, certain tendencies and aspirations become dominant in certain epochs, and that reforms and revolutions often come to the front simultaneously in countries widely separated from one another, and between which there are hardly any mutual relations.

The first ages of Christianity, the period of the Crusades, that of the Renaissance, of the French Revolution, present striking examples in illustration of this remark. It is also worthy of note that the literary movement known as Romanticism had its evolution almost simultaneously everywhere—even Japan shared in it; that the years 1830–31 and 1846–48 were much alike in different countries, and so-forth.

There are, beyond a doubt, epidemics of ideas. But with these, as with the foregoing classes of transmissions, *imitation* has much more to do than *direct communication*, and we must not let ourselves be carried away by fanciful conjectures. Suffice it to note *one element more* to be employed for the positive explication of a certain community of minds—an element, by the way, hardly noticeable in the general mechanism of history.

[1] *Milieu.* This word can generally be translated "atmosphere;" it never means "medium" in the spiritist sense. In the present instance "individual medium" means the totality of psychic states, habits, *psychorganic* associations, etc., peculiar to the recipient subject.—*Translator.*

When one comes to recognize the possibility of thought-transference, one naturally seeks traces of it even in antiquity. Rare it may be, yet that phenomenon cannot have escaped the attention of authors who have scrupulously noted extraordinary manifestations of human faculty. I shall be content with a few examples only, seeing the slight scientific value of these observations of the remote past.

St. Augustin relates that while he was a Manichæan he consulted soothsayers. Licentius, whom he introduces in his books against the Academicians, reminds him of the lucidity of a certain soothsayer named Albicerius. One Flaccianus went in search of Albicerius, after having planned to win an inheritance, and entertained the soothsayer with the intent to make him reveal this *secret* design, that so he might judge of the man's skill. The soothsayer straightway told him the nature of the business in question; nay, more—and this heightened the wonderment of Flaccianus—specified to him, without any hesitation, *the name of the inheritance*—a name so barbarous and so difficult that Flaccianus himself could hardly remember it. Furthermore, Albicerius divined the thoughts of those who asked him questions.[1]

"The remarkable thing in this narrative," says Morin, "is that the lucidity of the soothsayer is not at all attributed to a revelation from God or his auxiliaries, for St. Augustin, become a Christian, is recounting the doings of a Manichæan."

Similar facts are found in the lives of saints and among *ecstatici* of all religions.

"Thus, the parish priest of Ars, who died quite recently (1876), and whom they already talk of canonizing, read (so they say) the thoughts of those who came to consult him, and by the infallible accuracy of his vision disconcerted the skeptics that approached him to test and baffle him. Joseph de Cupertius, canonized under the name of Saint Cupertinus,[2] famous for his many ascensions, had the gift of reading *the thoughts of penitents who did not dare to confess to him certain big sins.*"

"Of course," continues Morin, "we cannot accept, without verification, all these wonderful tales. It is a pity they were not subjected to strict and judicious critical tests. But in examining facts like these we may draw comparisons that will throw some light on a subject of much difficulty."

Thanks to one of those vulgar errors imposed upon mankind by

[1] Augustini "Contra Academicos," lib. i., cap. 6, Nos. 17, 18; Abbé Flottes, "Etudes sur Saint Augustin," p. 19 *et seq.*; A. S. Morin, "Les Lucides d'autrefois" (*Union Magnét.*, p. 640, 1867).

[2] The name Joseph de Cupertius has a suspicious look; and of a certainty no worthy was ever canonized "under the name of Saint Cupertinus." In the original the whole paragraph is printed in small type and stands between quotation marks, but no author is named.—*Translator.*

fate,[1] some almost certain proofs of thought-transference were collected in the seventeenth century. I speak of the belief in the existence of demons and their incarnation in the bodies of certain unfortunates. This forejudgment, like all others, is not altogether groundless; the facts upon which it originally stood were real facts. It was the interpretation of them alone that was erroneous, and that showed a deplorable ignorance. The eccentricity of a terrible disease, which to-day no longer frightens us, thanks particularly to the celebrated researches of Mr. Charcot, and which often makes its appearance amid the favoring conditions of great *hypnotic sensibility*,[2] led observers in the past to believe that a force outside of man, a demonic power, was required to explain these manifestations. And since the devil cannot take possession of a baptized body save by consent of its soul, these wretches were burnt to make easier for them the expiation of their offense.

In this way our neuropathic heritage has been diminished, but at the same time we have lost a great number of excellent hypnotic subjects.

But we must not suppose that our forefathers would proceed heedlessly to condemn man or woman charged with demonolatry. On the contrary, one was declared to be *possessed* only after a strict examination.

A regular code fixed the conditions of the inquiry. According to the Ritual, the priest that was called on to exorcize was required, after having prepared himself by fasting, prayer and other good works, on leaving the altar after the mass, to take his seat, and with covered head *inwardly to command* the demon to give him a sign, and the demon, constrained to obey, had to reveal his name. Thus, according to the Ritual, the priest had to exorcise only patients that possessed the marvelous faculty of *reading unspoken thoughts.*

[1] *Un préjugé fatal de l'humanité.*

[2] "It is rational to suppose," says Mr. Paul Richer, "that the phenomena of hypnotism which always depend on a disturbance of the regular functionment of the organism, require for their development a special predisposition which, *with one accord*, authors place in the hysteric diathesis" ("Etudes Cliniques sur l'Hystéro-Épilepsie," p. 361. Paris, 1881). True, there is almost unanimous agreement on this point, but the authors are mistaken, I believe. It is not hysteria that constitutes a favorable ground for hypnotism, but it is *hypnotic sensibility* that affords a favorable ground for hysteria. Maximum hypnotic sensibility may exist without hysteria. Hysteria is a malady that develops at a certain age, and that may either disappear or become much modified, while hypnotic sensibility is an innate property that is nearly *constant* and as a rule persists through life. It is a question of temperament, of physiological constitution. If hysterepilepsy appears in this favorable soil—favorable not only to it, but also to many another disease, cholera, for example—the hysterepilepsy is *easily* curable by "hypnotism." I cannot give here the proofs of what I assert, and the assertion may seem strange and rash. It is based on long experience, and one will perhaps not take the trouble to verify it. Meanwhile, the reader may regard these few lines as a simple note not related to the matter in hand.

Of course, that was not the interpretation the exorcists gave of the words of the Ritual. On the contrary, they believed transmission of thought to be impossible; and if nevertheless the patient answered the mental questions, being in an hysterepileptic paroxysm, or in the state of spontaneous somnambulism, that was proof that his case was one not of disease, but of possession. It was believed that the devil, who is a spirit and an evil spirit, could discern thoughts, but that a person that was merely ill could not.

Father Surin,[1] in recapitulating the proofs of possession in the case of the Ursuline Nuns of Loudun, presents as one of the most indisputable the fact that *they told the most secret thoughts.* Of the many examples he gives of this faculty, I will quote only these two:

"The day after my arrival (he says), there was present at the exorcism a man who expressed to me a desire to see whether the demon knows our thoughts. I bade him make an order in his heart; and after he had done so, I constrained the demon to do what the man had ordered him. After giving me a few refusals he went to take from the altar the card on which is the gospel of St. John, and this man declared that he had in his heart ordered the demon to show the last gospel that had been read at the mass.

"One of our Fathers wishing to find if it were true that the demons know our thoughts, gave an inward order to the demon on duty (*en faction*), and then gave another; in short, in the space of an instant he gave five or six orders, and recalling them one after another, tormented the demon, saying, '*obediat ad mentem.*' The demon repeated aloud all the orders the Father had given him. He began with the first, then he said: 'But Monsieur does not wish.' Being at the seventh, he said: 'We shall see whether we shall do this, on which he has at last settled.'"

Among the other witnesses that affirmed the existence of thought-communication on the part of the Nuns of Loudun, we must quote the King's brother, who signed a certificate in which he declares that for several reasons he dare not doubt the possession. Among his reasons was the fact that a nun obeyed an order given by him mentally, without uttering a word or making any sign. Here is the passage in question:

"We, Gaston, son of France, Duke of Orleans, certify . . . . . And having wished once more to have a perfect sign of the possession of these women,[2] we concerted in secret and in a low voice with Father Tranquille, Capuchin, to order the demon Sabulon, who then possessed the said Sister Claire, to go and *kiss the right hand of Father Élysée,* his exorcist; the said demon obeyed strictly according to our desire, the which made us believe for certain that what the religious men laboring in the exorcisms of the said women had said to us of their possession is true, there being no appearance that such movements and knowledge of things secret could be attributed to human

[1] Bertrand, "Du Magnétisme," p. 321. Paris, 1826.

[2] *Filles*—unmarried women of any age.—*Translator.*

power. Whereof wishing to render testimony to the public, we have granted this present attestation, which we have signed with our own name, and had countersigned by the Secretary of our Commands, House and Finances of France this 11th May, 1635.

(*Signed*) GASTON."[1]

Prince Gaston, then, has this title to our gratitude—his only one, doubtless—that he made one of the first experiments in mental suggestion.

The Jesuit Surin made a good many more. He was able to declare, upon his conscience, that possession was a fact, and to swear before God and the Church that "*more than two hundred times*" demons had discovered to him "very secret things, hidden in his thoughts or about his person."

This revelation it was that decided the conviction of those hapless nuns, when proofs were no longer to be had, the devils refusing to do miracles.

Evidently the phenomenon of transmission was not manifested at all times, and it took a good deal of assiduous work on the part of Father Surin to obtain so imposing a lot of proofs. The exorcist—read *magnetizer*—thus acquired a personal influence over these subjects, an influence that prevented that of other persons from being exercised. The *ecstaticas* sometimes divined thoughts, but Father Surin must know beforehand what the thoughts were; else the thing did not work.

The Duke and Duchess de la Trémouille wished to repeat the experiment of the Duke of Orleans, only they took care not to communicate in advance to the exorcist the thought they wished to have divined. Three long hours they waited, but the demon did not divine anything. The same experiment was tried by two counselors of the parliament: the demon could not succeed in discovering their thought. To account for this, *a pact of silence* was alleged, shutting the demon's mouth.[2]

But in addition to these set experiments, there was a number of others that succeeded. The exorcists, who had got into their heads a whole hierarchy of demons, and who had adopted a preconceived theory, accusing the handsome priest, Urban Grandier (who was loved platonically by the nuns and most of his female parishioners), of having given up to the devil his own soul, and those of the sisters, *involuntarily communicated their a priori notions to the ecstaticas*, who did all they could to confirm them. The following interrogatory may serve as an example of this kind of suggestion:

"Hardly had Jane de Belciel noticed the magistrates when she

[1] "Relation de ce qui s'est passé aux Exorcismes de Loudun," etc. *See* L. Figuier, "Hist. du Merveilleux," vol. i., No. 205. Paris, 1873.

[2] Figuier, *op. cit.*, i., 218.

fell into violent convulsions. She acted in the most extravagant fashion, writhing on her bed, gesticulating, uttering plaintive cries. A Carmelite stood at the right of the possessed: Mignon (the Canon), who was on the left, began his exorcisms. Here is his first dialogue with the demon" (that is to say, with the patient's Unconscious):

"'*Propter quam causam ingressus es in corpus hujus virginis?*' (Wherefore did you enter the body of this virgin?)

"'*Causa animositatis*,' answered Jane de Belciel, still a victim of the convulsions. (Out of animosity.)

"'*Per quod pactum?*' (By what means?)

"'*Per flores.*' (By flowers.)

"'*Quales?*' (What flowers?)

"'*Rosas.*' (Roses.)

"'*Quis misit?*' (Who sent them?)

"'*Urbanus.*' (Urban.)

"'*Dic cognomen.*' (Tell his surname.)

"'*Grandier.*'

"'*Dic qualitatem.*' (Tell his station.)

"'*Sacerdos.*' (Priest.)

"'*Cujus ecclesiæ?*' (Of what church?)

"'*Sancti Petri.*' (St. Peter's.)

"'*Quæ persona attulit flores?*' (What person brought the flowers?)

"'*Diabolica.*' (A diabolic one.)

"It is evident that there were in this interrogatory suggestions, and they not mental only, and that on the other hand the examiner had neglected to clear up certain answers of the patient; so the proceedings did not seem entirely correct to the magistrates present at the exorcism.

"'It would have been well,' said the civil lieutenant, 'had the possessed been interrogated as to the cause of the animosity of which she has spoken.'

"'I am not allowed,' answered the priest, 'to put indiscreet questions.'

"'But it seems to me,' the lieutenant made bold to say, 'that that question would not have been more indiscreet than the others—than that, in particular, whereby you procured the name and surname of Urban Grandier to be given to you.'

"Thus, then, did the devil in the first interrogatory reveal his presence. But such was not always the exorcist's thought, or at least the *ecstatica* did not always divine just what he wanted her to say. From this resulted some amusing contradictions. Here is another interrogatory conducted by another exorcist, named Barré, in presence of the *bailli* and four physicians.

"The mass having been performed, Barré came forward to give the communion and thereafter to exorcize. Holding in both hands the blessed sacrament, he said to the possessed:

"'*Adora Deum tuum, Creatorem tuum.*' (Adore thy God, thy Creator.)

"She answered:

"'*Adoro te.*' (I adore thee.)

"The exorcist, a little taken aback by this answer, resumed his questioning.

"'*Quem adoras?*' (Whom do you adore?)

"'*Jesus Christus*,' she answered with a solecism.

"Whereupon one of the assessors of the provost, Daniel Drouin, could not help saying quite aloud:

"'There's a devil that is not grammatical.'

"The exorcist, a little disconcerted, repeated the question, taking care, however, to modify his phrase so as to bring the nominative case (which had just been employed amiss) into the answer.

"'*Quis est quem adoras?*'

"But the possessed, conscious that she had made a slip in grammar, chose to set matters right by employing the vocative case—which came in no less amiss.

"'*Jesu Christe*,' she answered.

"'There's bad Latin,' exclaimed several persons present, but the exorcist held that the answer was '*Adoro te, Jesu Christe*,' and the grammatical dispute was not carried any further."[1]

But if the devil was not quite correct in his Latin, still he was rather accommodating, for he recognized Jesus Christ as his master.

Someone, perhaps, will be surprised to find these nuns speaking Latin, but they had some little knowledge of it, being obliged to explain the creed and the paternoster to the novices; they heard Latin every day all around them; and in ecstatic states the memory is often highly developed. Sick patients and somnambules have been known to pronounce several phrases in languages of which they knew nothing in the normal state, but which they heard spoken in their childhood. Finally, the transmission of thoughts was sometimes added to other causes. When that failed and the possessed knew not what reply to make to a question put in Latin, she would say "*Deus non volo*," instead of "*Deus nonvult*."

When a question was asked in Greek or Hebrew, there was no answer. Sometimes, however, thought-communication helped in such cases.

Finally, there was still another phenomenon that led people to believe in the gift of strange tongues: the *ecstaticas* sometimes spoke a language entirely unknown.

It is known that now and then, particularly in spells of good humor, one will utter odd sorts of words, senseless combinations of syllables. This tendency is seen in the *argot* of students and children. Some ecstatic and convulsive states exhibit this caprice of our automatism in a peculiar way. The *ecstaticas* of early Christian times also spoke unknown tongues.

"I have already observed (says Carré de Montgéron) that it is in the height of their ecstasy that many convulsionaries pronounce those discourses in unknown or foreign languages. I must add that they do not themselves understand the purport of them save at the moment, while they are pronouncing them, and that they remember them no more, or at best only in a general way, the instant their discourse is over."[2]

"The same phenomenon was seen among the first Christians. St. Paul shows this plainly in sundry places: 'He that speaketh a

[1] Figuier, *op. cit.*, 108.

[2] Montgéron, "Idée de l'État des Convulsionnaires," p. 89.

tongue,' says he (1 Cor. xiv.), 'speaketh not to men but to God, for none understandeth.' Elsewhere he says in effect that these tongues are but signs to procure the conversion of unbelievers." (Bertrand, 325.)

But sometimes one cannot explain the answers of the possessed, except by thought-transference. Here are some instances of this sort, taken from Lamenardière's "Démonomanie de Loudun:"

"Mr. Launay de Barillé, who had lived in America, declared that, on a visit he made to Loudun, he had spoken to the nuns the language of certain savages in that country, and that they had answered him very aptly."

We are not told what words these were. If they were, as is probable, only such expressions as "Good-day," "How do you do?" the very tone of the phrase might betray the meaning. But here is a more detailed narrative:

"The Bishop of Nîmes having put questions in Greek and in German, got satisfactory answers to both. He ordered (in Greek) Sister Claire *to lift her veil* and to *kiss* the grille[1] at a spot he designated. She obeyed him, and did several other things that he desired of her. On this occasion it was said publicly of this prelate that he must needs be either an atheist or an idiot if he did not believe in possession.

"Some physicians, too, questioned them in Greek upon the terms of their science—terms very difficult and known only by the learned in their profession; the nuns explained them clearly.

"Some gentlemen of Normandy certified in writing that they had interrogated Sister Claire de Sazilly in Turkish, Spanish and Italian, and that her replies were quite apt."[2]

Carré de Montgéron[3] speaks of a young lady, Dancogné, who, though she never had any voice, used to sing canticles in an *unknown* tongue. (I have myself observed similar facts in the state of *somnambulic delirium.*) "But," says Montgéron, "what is more surprising is, that it often happens to her, in certain times of ecstasy, to understand the meaning of all that is said to her in whatever language it may be spoken, and to make reply in a perfectly apt way to all; a multitude of people have witnessed this."

Bertrand justly remarks that very few cases indeed are recorded in which the answer is given in the same language, and in those cases the foreign tongue was more or less known by the patient, whereas in the great majority of cases the patient understands the language (that is to say, the thought) but does not speak it.

Evidently it is easier to get at or divine the meaning of a phrase spoken with a certain intonation, than to fish out foreign words in the

[1] The grating that separates the outer reception room from the cloistered portion of a nunnery.—*Translator.*

[2] Pilet de Lamenardière, "La Démonomanie de Loudun," etc., p. 26. 2d ed., La Flèche, 1634.

[3] *Op. cit.*, p. 53.

mind of one that knows that foreign tongue, in order to reply to him in the same.

"As for somnambules (says Bertrand), magnetizers are not wont to exercise them in giving replies in unknown languages, and I can quote only one fact of that kind. It was reported to me by an estimable man, a physician of great learning, too early taken from science and his friends. He had a somnambule that presented to him the most marvelous phenomena, and who understood him when he spoke Greek, Latin, or English. One day he decided to *read* to her a few lines in English. 'Do you expect me to understand your gibberish?' she asked. 'But,' the doctor replied, 'I spoke to you a moment ago in the same tongue and you understood me.' 'Then it was your thought I understood,' answered the somnambule, 'and not your language.'"

"August 6, 1634 (writes Lamenardière) John Chiron, Prior of Maillerais, wishing to be confirmed in the belief he had in 'possession,' said in a low voice in the ear of Blaise de Fernairon (Canon) that he wished the nun to open the Missal that was by the grille, and to put her finger on an *introit* beginning with the words '*Salve, sancta parens.*' The exorcist bade her to obey according to the intention of the said Sieur Chiron. *She fell into strange convulsions*,[1] and uttered several blasphemies, and though she had never seen the said Sieur, she called him Prior of Maillerais, and, after several orders reiterated for an hour, she took the Missal, which lay on a shelf by the grille, and said, 'I wish to pray to God,' and turning her eyes in another direction, she put her finger on a large S, at the beginning of the *introit* of a Mass of the Virgin, the opening words of which are '*Salve, sancta parens*,' which the said Prior seeing, he said that was the sign he had asked for."[2]

"June 20, 1633, a priest of Saint-Jacques-de-Fouars, desiring to make proof of divination of thought, in a low voice asked the exorcist to make the possessed bring five leaves of a rosebush. The exorcist ordered Claire de Sazilly to obey. The nun went out and into the garden, whence she brought first a marigold and some other herbs, and presented them at the grille, with much crying, saying to the Sieur de Morans: 'Is that, Father, what you *ask? I am no devil, to know your intentions.*' Whereto he replied simply, '*Obedias!*' (obey!) She went back to the garden, and, after many repeated orders, presented at the grille a small sprig of rosebush on which were *six* leaves. The exorcist said to her, '*Obedias punctualiter sub pœna maledictionis!*' (obey precisely under pain of a curse!) She now broke off one leaf, and presented the sprig to him, saying, 'I see that you want only five, the other was not of the number.' The Prior was so content with what he saw, and so moved, that he went away with tears in his eyes."[3]

In the same work we find recorded many similar cases. For instance, Sister Claire kneels by mental order of her magnetizer exorcist; she divines the day when the Chevalier de Méré last confessed, and repeats words that were heard by the exorcist alone; and so on.

[1] See Mr. Gibert's experiment, p. 90, *supra*.

[2] Pilet de Lamenardière, "La Démonologie," etc., p. 26.

[3] *Id.*, p. 27.

The latter class of facts, namely, suggestion or penetration of thoughts, seemed impossible to Aubin (author of the "Histoire des Diables de Loudun"), who was overmuch afraid lest he should be forced to believe in Dæmonomania. He gives only one instance of suggestion, the one witnessed by Prince Gaston, May 10, 1635.

Another author, Dr. Calmeil, no less scrupulous, but more impartial, after having seen that artificial somnambulism produced some of the effects for which people wanted to hold the demons answerable, adds: "On a hundred occasions indeed, we may believe, the energumens (the possessed) read the thoughts of the religious men charged with the duty of fighting the demons."[1] "*Read the thoughts of the religious men*, who gained a powerful influence over them," remarks Figuier, "and not the thoughts of other persons."

This remark is applicable in the majority of cases. We may, however, recall some experiments in mental suggestion made by me upon Mrs. B. (*magnetized by Mr. Janet*), and who had not seen me while she was in the waking state (p. 85, *supra*).

We find the same phenomenon among the prophets of the Cévennes; so, too, among the Convulsionaries of Saint-Médard. "Add," says Dr. Bertrand, "that Madame Guyon, that mystic devotee, famous for the admiration that the virtuous Fénelon professed to have for her, tells in the history of her life, that often she used to read the thoughts of Father Lacombe, her confessor, as he read hers; 'I saw,' she says, 'that men might, in this life, learn the language of the angels; little by little I was reduced to speaking to him only in silence.'"

It is to be remarked that the conversations of these two pious souls probably were ever about the same questions, and that consequently the divination was not always difficult.

Let us now turn to the somnambules:

"Among the somnambules that I have magnetized (says Bertrand), I never found one that presented communication of thought in any high degree. Nevertheless, I can cite two facts of which I am personally cognizant. The first is found recorded in my 'Traité du Somnambulisme' (p. 247). The case was that of my first somnambule, on whom I was performing the processes by which I had been accustomed to awaken her, while, at the same time, I willed strongly that she should not awake. Instantly she had violent convulsive movements. 'What is the matter?' I asked her. 'How is this?' she replied; 'you tell me to awake, and you want me not to awake.'"

This experiment is very conclusive, but it is rarely successful, for the ideorganic association formed between certain gestures and sleep, produces sleep by force of habit, the weak, purely mental opposing influence notwithstanding.

"The other instance coming under my personal observation is found at page 279 of the same work. A poor woman, uneducated, not

[1] Calmeil, "De la Folie," vol. ii.

able to read, could, I was told, understand in somnambulism the meaning of words the signification of which was unknown to her in the waking state; and, in fact, she explained to me most accurately and most ingeniously what we were to understand by the word *encephalon*, which I proposed to her: a phenomenon which, if you do not wish to regard it as chance—a supposition as hard to admit, perhaps, as the faculty itself, that the phenomenon supposes—can only be explained by recognizing that this woman read in my very thoughts the signification of the word about which I had questioned her."

This fact, too, is worthy of attention, and for this reason: If we compare the diagnostic pronouncements of somnambules recorded in the writings of magnetizers who themselves did not possess compepetent knowledge of anatomy, with the pronouncements of somnambules directed by a physician (for example, the 35 observations of Dr. E. Louis de Séré),[1] we find a great difference as regards precision. The same is to be said of psychological and other questions.

Unless we hold that none of the physicians that made these experiments could refrain from verbal suggestions, even while his precise object was to get at the truth, we must admit, here and there, transmissions of thought like those we have quoted from Bertrand.

The first person to call the attention of observers to the phenomenon of mental suggestion in artificial somnambulism, was the Marquis de Puységur. In his writings we find a great number of facts. Here is how he relates his first experience, in a letter of March 8, 1784, addressed to a member of the Harmony Society. In the first place, he apologizes for the enthusiasm awakened in him by his first attempts at magnetic treatment, begun "in play" (*en plaisantant*) and which had surprising results. Then he continues thus:

"These trifling successes led me to try whether I might be of service to a peasant, a man of 23 years, who for four days had been confined to his bed by an attack of pneumonia. I went therefore to see him: it was last Tuesday, the 4th of this month, at 8 o'clock in the evening. The fever was growing less. After having him taken out of bed I magnetized him. What was my surprise to see him, after half a quarter of an hour, *fall asleep* quietly in my arms, without convulsions, without any pain. I pushed the crisis [*i. e.*, he kept on magnetizing], and that produced vertigo. The man talked, speaking in a loud voice about his affairs [somnambulic ravings]. Judging that these thoughts might affect him injuriously, I sought to inspire him with more cheering thoughts. [The somnambulism therefore was not very active, and was akin to aideia and to a suggestionable state intermediate between aideia and polyideia.] To do this needed no great effort; then I saw him satisfied, imagining himself to be drawing for a prize, dancing at a festival, etc.

"These thoughts I encouraged in him, and so forced him to take a good deal of exercise in his chair, as though dancing to an air which, by singing it (*mentally*), I made him repeat aloud. By this means, from that day on, I occasioned in the patient an abundant perspiration.

[1] "Application du Somnambulisme Magnétique au Diagnostic," etc. Paris, 1855.

"After an hour of crisis, I quieted him [that is to say, awakened him], and left the chamber. A drink was given him. Having procured for him some bread and bouillon, I made him eat that very evening a soup—a thing he had not been able to do for five days. He slept soundly the whole night [amelioration of the natural sleep is an almost constant phenomenon in magnetism], and the following morning *had no recollection of my visit of the evening before;* he told me of his bettered state of health."

That experience was the starting-point of modern somnambulic magnetism. Some time after, Puységur, always enthusiastic about his successes, wrote as follows to his brother concerning Vielet:

"When he is in the magnetic state, he is no longer a simple hind scarcely able to phrase an answer, but a being I know not how to describe. *I have no need to speak to him; I think fornent him, and he understands me, answers me.* When anyone enters his chamber, he sees him *if I will it;* talks to him, tells him the things *I will that he tell him, not always as I dictate them to him*, but as truth requires. When he wishes to say more than I deem it prudent that people should hear, *then I stay his thoughts, his phrases, in the middle of a word*, and change his thought completely."[1]

He did not find, it seems, many somnambules of this stamp, for he has less to say about them in his two later writings: "Du Magnétisme Animal considéré dans ses rapports avec diverses Branches de la Physique générale," Paris, 1807; and "Recherches, Expériences, et Observations Physiologiques sur l'Homme," Paris, 1811. But he laid the more stress upon the appreciation of diseases, and he still believed that his will was the one sole agent—plainly an exaggeration.

The fact is, one always feels the effect of a first experiment; and this time a school was formed under the influence of this first impression of the master.

It is so in our day, and I hardly find more of prudence or of circumspection in the writings of medical men who, after having sophisticated an hysteric, believe themselves competent to lay down physiological "laws," and to settle in accordance with their individual convictions the most delicate and most complicated questions.

As for the old-time magnetizers, who spent their lives in studying these problems, sometimes without sufficient preparation, but at the same time without presumption, we do not read them nowadays; we just append to their names the epithet "charlatans." Some have adopted a more profitable method: they glean here and there an observation made by some old-time magnetizer, and having sophisticated it, and, above all, put their own brand upon it, take to themselves the credit of discovery. But let us proceed.

[1] Puységur, "Mémoires pour servir à l'établissement du Magnétisme," pp. 22, 29, *et seq.*

Some time after Puységur, a distinguished physician of Lyons, President of the Medical Society of that city, was led to investigate the more striking phenomena of magnetism. He was skeptical, and an opponent of mesmerism, but it so chanced that he was forced to recognize a series of facts far more extraordinary than anything announced by Mesmer. His researches on catalepsy, on the action of the magnet, of electricity and of metals, on the phenomenon known as "transposition of the senses," etc.; finally, on the subject that engages our attention here, mark an epoch in magnetism. They are to-day absolutely unknown; but as already *just a century* has elapsed since he observed certain facts, I have no doubt that some fine morning they will tell you that a hypnotizer in Lyons or in Paris has *discovered* them anew, and that, thanks to his ingenuity, his authority, and the general ignorance of history, a new "hypnotic" school has sprung up.

In the meanwhile let us note the facts that concern our subject. This is how Petetin[1] was led to employ magnetism for the first time:

"The patient was sinking day by day. She had hardly two hours' sleep in a night; she could take no nourishment except chicken broth, milk, and pounded ice. Petetin, her physician, possessed by the idea that the excitation of brain and nerves was caused by superabundant electricity, bethought him of making very strong aspirations fornent the patient's nostrils, to abstract this excess of electricity; but that method had no effect. Then, *laying one hand on the forehead and the other on the epigastrium*, he made another aspiration. Mrs. X. opened her eyes, but they were dull and fixed; at a second aspiration they resumed their brightness; a few minutes later, the fit, which used to last two hours, was over. At his subsequent visits the doctor substituted expiration for aspiration, and in eight days all the symptoms of this extraordinary malady had disappeared through this simple means, 'the effects of which,' says he, 'are as evident as the cause is hidden.'

"He adds that as the cure progressed, the faculties of the cataleptic patient acquired a new power. 'Not only did she foresee what was about to happen to her, but if one *conceived a thought without manifesting it by speech*, she was cognizant of it at once, and did whatever one had the intention to bid her do, *as if the decision had come of itself;* sometimes, however, she would ask that the mental order might be suspended or revoked, when the act ordered was beyond her strength, or if she was fatigued.'"[2]

Petetin made upon another cataleptic, Mrs. de Saint-Paul, a great number of experiments, and he invited, to be witnesses of these,

[1] Dr. Petetin, "Mémoire sur la Découverte des Phénomènes que présentent la Catalepsie et le Somnambulisme." Lyons, 1787. "Électricité Animale prouvée par la Découverte des Phénomènes Physiques et Moraux de la Catalepsie Hystérique." Paris, 1808.

[2] Foissac, "Rapports et Discussions sur le Magnétisme Animal," p. 369. Paris, 1353. Figuier, "Hist. du Merveilleux," vol. iii., p. 292.

several of his professional associates and other persons, as Messrs. Eynard, Colladon, of Geneva; Domenjon, Dolomieu, brother of the naturalist, and Jacquier, administrator of the Lyons hospitals. Eynard, the most incredulous of them all, came one day to the lady's house and found her in one of her fits, alone with a nurse. He had with him several drawings that he had made by electricity.[1] He held near the epigastrium of the patient the portrait of Louis XIV., and asked whether she recognized it. She gave an affirmative movement of the head. "Is it Francis I.?" Negative sign. "Louis XV.?" Same response. After several other names he pronounced that of Louis XIV.; she answered "Yes." Mr. Eynard having been assured that cataleptics are able to read the thoughts of persons in rapport with them, he asked her once more, in order to verify the fact, whether she knew the author of the drawing. Affirmative sign. He tried to mislead her by naming sundry persons, but she did not answer "Yes" till he had named himself. Say what he would about his being unable to draw, the patient only shrugged her shoulders; the more he denied, the more strongly she showed her impatience by characteristic gestures. Asked at last by what means he had produced the portrait, she pointed toward an electrical machine that was near her bed and which Petetin employed in treating her complaint.[2]

Soon people at Lyons talked of nothing else but the wonders of somnambulism, and no doubt Petetin's researches would in the end have won the attention of men of science, had not the Revolution broken out. "Nothing short of the cannon of the Revolution," says Figuier, "could have silenced in that town the discussions on magnetism. But at the time all this hubbub subsided, in Lyons as elsewhere, not because magnetism was forgotten, but because its adherents were scattered."

Petetin was forgotten, and died in 1808, without so much as printing his important treatise on "Animal Electricity," which appeared some months later. The work is now very hard to find.

The priest Faria,[3] a bold and truly original experimenter, held the attention of the public for a while about 1815. He is the father of the *Suggestionists* of to-day. He acted only by verbal suggestion and did not believe in will-transmission: thus he was in absolute opposition to the *Voluntists* of the Puységur school. As his one purpose was to produce effects in public, it is not surprising that he should have

[1] Our author prints this paragraph in brevier, but without quotation marks, so indicating that the statements it contains are given on the authority of the writers named in the next foot-note.—*Translator.*

[3] "De la Cause du Sommeil Lucide," etc. Paris, 1819.

failed to obtain a phenomenon that requires long and patient research in seclusion.

A third school, one more directly connected with Mesmer, was that of the *Fluidists*, represented by the learned librarian of the Paris Jardin des Plantes, a most conscientious worker, cautious and reserved, whose principal work, the fruit of *twenty-five years'* observation (I do not mention this detail to frighten the hypnotizers of to-day), appeared in 1813.[1]

Deleuze, as we know already, was familiar with the phenomena of transmission; he even glimpsed the benefit that might accrue to science from bringing into the domain of positive knowledge a great number of facts previously incomprehensible, and of a kind to lend support to vulgar errors (*préjugés*). But he does not concern himself much with these phenomena, for two reasons: First, he wished, especially in this first edition, to avoid everything that could offend the incredulity of the academic bodies; and then he regarded as unfitting all experiments made for curiosity' sake, *i. e.*, whatever has not for its principal end the cure of diseases. But so strongly did he believe in the community of thoughts between the magnetizer and his subject, that he says with a charming simplicity: "When one wishes to ask anything of the somnambule, he must express his wish in words. Good somnambules understand what you wish without your speaking. But why employ that means without necessity? It is an experiment, and we ought to have it made a law to deny ourselves all experiments."[2]

The reader will perhaps be surprised to see that in Deleuze's time this prohibition of experimentation was scrupulously respected by very many observers. Volumes were published upon the therapeutic application of magnetism, but the scientific experimental part made no progress. There were cures, that is all. It was only by accident, therefore, that mental suggestion was observed.

But certain magnetizers studied the question a little, and have left some interesting observations. I will quote all of these that have a right to our confidence, trying, as far as possible, to separate thought-transference from will-transference, which will be considered later.

Transmission of ideas and words, or of thoughts in general, presents itself in several forms:

1. *Direct Experiments.*—These are least numerous. To this class belong the experiments of Drs. Teste, Puel, Comet, Barrier, Perronet, and of Messrs. Lafontaine, Maricourt and Souchère. But it is, above all, the quite recent experiments of Professor Barrett, of the English Society for Psychological Research, that have revealed this phenomenon to us.

[1] Deleuze, "Histoire Critique du Magnétisme Animal." Paris, 1813.

[2] Deleuze, "Instruction Pratique sur le Magnétisme Animal," p. 135. Paris, 1825.

2. *Experiments in Apparent Vision*, which have been much more numerous, and in which thought-transference and transmission of recollections have been confounded with actual vision of near or distant objects. Under this head we will cite the observations of Dr. Charpignon, of Messrs. Tissot, Jolly, Baragnon, Lafontaine, Robert-Houdin, and General Noizet.

3. Finally, we shall have occasion to mention the fact that thought-transference is by accident associated with other classes of facts, especially in pseud-hypnotism.

Let us begin with the experiments of the English Committee, which are quite recent and which were the best controlled. The reports upon these researches already fill a volume, and I can reproduce only a few instances. I will, however, give in full the report of the experiments of December 6, 1884. They were made in presence of Mr. Guthrie and Professor Herdman.

Mrs. Relph, the subject, is seated, and the objects chosen for the experiments are concealed by a screen behind her back. The experiments take place without contact.

OBJECT THOUGHT OF.	OBJECT DIVINED.
1. Piece of red paper cut in the form of a small egg-cup with white egg in it.	Something red; longer than it is broad.
2. Blue paper in shape of a pitcher.	'Tis blue. 'Tis wider at top than in the middle, then wider again. 'Tis like a pitcher (draws figure of a pitcher).
3. Red paper cut in form of a vase.	'Tis red. I can see only the color.
4. A new rasp.	Something shining—silver or steel —long and thin.
5. A wooden disc on a dark ground.	I cannot make that out.
6. A red disc.	'Tis red; 'tis round and red.
7. Same object as in No. 5.	Is it something red all around?—reddish yellow — something light.
8. Silvered paper cut in shape of a teapot.	'Tis of bright silver, like a boiler —'tis a teapot.
9. A yellow oblong rectangular figure.	It is longer than wide.
10. A sovereign.	Is it bright yellow?—gold?—is it round?
11. Three of hearts.	Is it a card with red spots? A tray or something like that.
12. Five of clubs.	Another card, with five black spots?
13. Eight of diamonds.	A card with a good many spots? Red—a ten.
14. A card with two red crosses.	Something yellow and bright. I don't see well. Is it a card with red spots? I do not see.
15. No object. We think of a white cross on a black ground.	I see something white and black —I see two lines.

I commend this series to the attention of Mr. Preyer, and invite him to do the same thing by drawing lots.[1]

Let us now see what the magnetizers say:

"At Tours (says Mr. Lafontaine) I had a somnambule that was gifted with great lucidity. Mr. Renard, steward (*proviseur*) of the college, a man strongly skeptical, came each day bringing objects carefully wrapped up, and which he kept in his pockets. No sooner was he in rapport with Clarissa, the somnambule, than she named to him the object he had so carefully concealed. To prove to him that it was really *thought-transmission* and not *sight*, I had a mental order executed, that is, without my uttering a word or making any sign; but concentrating my thought upon any act the performance of which I wished, the somnambule rose from the chair and did what I willed."[2]

2. "Dr. Thomas presented to Clarissa his small lancet case, asking her what was inside. The somnambule answered that it contained only three instruments, and told him where he had left the fourth."[3]

3. "Sometimes Mr. Renard would fasten the doors and the shutters of his study, stopping the keyholes so that no one might see him; then he would light a candle and write a few words, and wrap several papers around what he had written. He would come with an air of triumph, hoping, after all the precautions he had taken, that the somnambule would not be able to see what he had written. But the instant he had put the paper in the girl's hand, *sometimes even before he had taken it out of his pocket*, Clarissa would tell him what he had written."[4]

4. "Mr. de la Souchère, educated at the Polytechnic School, an able chemist of Marseilles, had as a domestic servant a country woman in whom somnambulism and several of its noteworthy phenomena were produced with great ease. 'In magnetic somnambulism,' says he, 'Lazarine entered into most complete communication of thought with me, and *so insensible was she* that I used to drive needles into her flesh, into the roots of the nails, yet she would not suffer the slightest pain, nor would there be a drop of blood. [This phenomenon is very common; there is produced often in somnambulism a notable contraction of the small vessels.] In presence of the engineer, Gabriel and some friends I have made the following experiments: I would make her drink pure water, and she would tell me it had the taste of whatever liquid I was thinking of—lemonade, syrup, wine, etc. It was proposed that I should make her drink sand. She was unable to divine [the order]. Then I put sand in my mouth, and straightaway she began to spit, saying that *I was giving* her sand. [Transference of sensation.] I was then behind her and it was impossible for her to see me. [A similar experiment, but still more striking, is quoted by the Count de Maricourt: the subject, having drank *in the*

[1] Mr. Preyer, professor of physiology at Jena, has criticised the researches of Mr. Ch. Richet, declaring that he obtained by simple chance the same results. ("*Die Erklärung des Gedankenlesens nebst Beschreibung eines neuen Verfahrens zum Nachweise unwillkürlicher Bewegungen.*" Leipsic, 1886.)

[4] *Ib.*

waking state a glass of water, under mental suggestion of a glass of *kirschwasser*, manifested all the signs of intoxication *for several days*. I would remark that when such phenomena are produced in the waking state it is harder to do them away than when they are produced in somnambulism. It is phenomena of this sort that lead magnetizers to believe that, by magnetizing a glass of water or any other object, they can impregnate their "fluid" with different physical and chemical properties. The magnetization is of no effect in such case, for it is the thought that acts, and not upon the object, but upon the brain of the subject.] Some one sends me a book (Robinson Crusoe.) I open it and examine an engraving representing Robinson in a canoe. Lazarine, being asked what I was doing, answered: 'You have a book; you are not reading; you are looking at a picture; there is a boat and a man in it.' I bade her describe to me the furniture of a chamber that she did not know, and she described the articles of furniture *precisely as I represented them to myself.* I have not been able to see in my domestic transposition of the senses. Different objects would be applied over the epigastrium: *if I knew what they were, she would describe them;* if I did *not* know what they were, she was unable to name them. It is possible that, in certain cases, what has been accounted transposition of the senses is only transmission of thought."[1]

5. Dr. Teste[2] has again and again found that the somnambule can follow the magnetizer's thoughts. "Miss Diana," says he, "had a conversation with me in which I spoke only mentally." He cites, furthermore, an extraordinary experiment wherein mental suggestion appeared as an *hallucination.*

"One day," he writes, "I imagined a wooden railing round about me, but spoke not a word. I put in the somnambulic state Miss H., a very nervous young person, and asked her to fetch me my books. Coming to where I imagined the railing to be, Miss H. halted, saying they had set up a railing there. 'What a singular idea,' she said, 'to have put a railing in this place!' If you take her by the hand to make her go beyond, her feet are riveted to the floor, the upper portion of her body alone is projected forward, and she says you make her stomach press against the obstacle."

And here is a highly interesting fact recorded by Dr. Bertrand in one of his lectures on magnetism, reproduced by Noizet:

6. "A magnetizer deeply imbued with mystic ideas had a somnambule who, in his sleep, saw nothing but angels and sprites of all kinds. These visions served more and more to strengthen the magnetizer's religious belief. As he was always quoting his somnambule's dreams in support of his system, another magnetizer undertook to undeceive him by showing to him that no somnambule has such visions as he told of, except so far as they existed first in the magnetizer's brain. To demonstrate this assertion, he proposed to make the same somnambule see *all the angels of heaven at table together, and eating turkey.* So he endormed the somnambule, and after a while asked him if he did not see something extraordinary; the somnambule replied that

[1] Dr. Despine, "Etude Scientifique sur le Somnambulisme," p. 221. Paris, 1880.

[2] Teste, "Manuel Pratique du Magnétiseur," 4th ed., 1854; and "Le Magn. Anim. Expliqué," p. 243, 1845.

he saw *a great company of angels.* 'And what are they doing?' '*They are around a table and are eating.*' But he could not tell what dishes they had before them."[1]

In general, if the somnambule thinks he *sees* something out of the ordinary course of things, the first question is, whether that is not due to simple involuntary suggestion on our part.

7. "A student of medicine asks one of my somnambules what patients the jury will give him for examination as his test for the doctorate. She described very accurately three patients in the Hôtel Dieu who had more particularly attracted the attention of the student, and whom he would have *wished* to be made the subjects of his examination. She even added—a characteristic detail—with regard to one of the patients: 'Oh, what a bright eye that woman has—and fixed! It makes me afraid, that eye!' 'Does she see with that bright eye?' asked the student. 'Hold! I do not know—it is hard. It is not natural. What is it made of? Something—something that breaks—and shines. Oh, she is taking it out—putting it in water,' and so on. The patient had a glass eye; this fact, of which I was quite ignorant (for I did not know the patients in question), but which was known to the student that was questioning the somnambule, was *described* accurately by her. Whence did she get the image? From the questioner's psychism, which, through mine as an intermediary, was reflected in her.

"It is right to add that the somnambule's predictions were not fulfilled; that on the day of his test the student had to examine other patients, and that those described by the somnambule were not even mentioned."[2]

"As a rule," says Dr. Charpignon, "second-sight is confounded with the phenomenon of thought-transmission. Thus, most of the experiments that are cited consist in asking the somnambule to go to your home or to a place known to you. You are in rapport with him and he usually describes to you places or objects with the utmost precision. Now, in all this there is, as a rule, no real vision: the somnambule sees in your thoughts the images you trace therein. The more attentively you follow him and direct his descriptions (namely, by helping him with verbal suggestions), the more perfect they will be."[3]

But this is of rather rare occurrence. I have observed only one case of this kind. That was some time ago, and as I did not believe in mental transmission, I regarded the fact as the result of circumstances that it was impossible to verify. According to the person that consulted the somnambule, the latter had described exactly to him his house and garden. But Charpignon is quite right in saying that if there be such a thing as vision at a distance, it has usually been apparent only, leading astray magnetizers that were not exacting.

[1] Noizet, "Mémoire," p. 128.

[2] Perronet, "Du Magn. Anim.," p. 34, 1884.

[3] Dr. Charpignon, "Physiologie, Médecine, et Metaphysique du Magnétisme," p. 90.

They wrote a few words, for instance, on a bit of paper, then folded this carefully; the somnambule clapped it on his own person anywhere, and "read" the contents. It was Dr. Teste, I believe, who, believing he had a case of second sight, broke down completely in his experiments before the Academic Commission of 1840, when a bit of writing shut up in a box, and the contents of which he did not know, was to be "read" by the somnambule. It need not be added that certain *bona fide* magnetizers, among them Mr. Hublier, have been simply tricked by their somnambules.[1]

Mr. Henry Joly,[2] who does not believe in clairvoyance, nor in thought-transference, relates the following:

8. "We have from an honorable magistrate, one of the most sympathetic auditors of our courts, the minutes of an inquiry or *expertise* made by him in the case of a somnambule, whose practices had been brought under the notice of the officers of the law. This magistrate was of the opinion that the somnambule was honest and that she was really endormed. Monday, July 4, 1859, he said, I repaired at 8.40 A. M. to the house of the B's., husband and wife, living in C. S. S., St. G. Street. I asked Mr. B. to put his wife in the state of magnetic sleep. The woman has been *blind* for 2 years, does not distinguish objects, and has but a dim perception of light through the left eye. Mr. B. had told me that I might interrogate his wife; I put into her hands a white handkerchief, and the following dialogue took place: 'Can you tell me what mark is on this handkerchief?' 'Very easily; but who gave you this handkerchief?' 'Answer my question. This handkerchief is mine; I bought it.' '*The mark that I have under my fingers* is pretty hard to read. But I see an M.; I cannot read the letter that is before it' (the mark on the handkerchief is J. M., on red cotton, in Gothic letters). . . . . .

"'What is the age of the person to whom this lock of hair belongs?' 'It is a young person.' 'Can you conduct me to that person?' 'No; for the person is no more.' 'You have divined aright. Can you read the letters written *on the inside of this medallion?*' 'It is pretty hard. I will try. . . . No; I cannot read.'

. . . . . .

"'Could you tell me whether I have on my body a fresh wound, and where?' 'Yes; you have one on the leg, or rather not a wound, for it is closed.' 'On which leg?' 'It is on the left.' (That was correct, but she was in error as to the precise place.) 'I hand you this lock of hair wrapped in paper. Examine it.' 'It is not blond like that you showed me a while ago; it is *very dark brown.* What do you mean to do with it? Take it to my neighbor, R.; *he makes hair-work mementoes in very fine style.*' 'Tell me whose hair it is.' (The somnambule is much fatigued; she hesitates for a good while without replying.) 'Does it belong to a man or to a woman?' 'To a woman.' 'You are mistaken.' 'Yes, I was mistaken. I thought you intended this hair to be worn by a woman; that is what I meant to say.' 'Tell me whether I have much love for the person to whom this hair

[1] Burdin and Dubois, "Histoire Académique du Magnétisme Animal," p. 584, *et seq.* Paris, 1841.

[2] H. Joly, "L'Imagination, Etude Psychologique," p. 60. Paris, 1877.

belongs.' 'So much that one cannot have more.' 'Do you know what that person is to me?' With a little impatience: 'I have told how you loved the person. It is with family affection, that is plain; it is the bond of blood; I cannot say anything else.' The hair was very dark brown; it was a lock cut from the head of my only son by his mother, who intends to have a bracelet made of it for herself."

The author from whom this observation is taken does not believe in clairvoyance, and plainly there is in this instance no *clairvoyance* proper; but it were difficult, I think, to explain the facts unless there were some traces of thought-transference in spite of the verbal suggestions, which are not wanting.

Another skeptic, Mr. Tissot,[1] gives his own experience:

9. "*Seance of Sept.* 4.—Sixty pulsations a minute, before the sleep as after; but at the moment of sleep and before the feigned or real convulsion (there was no convulsive movement in the two latest seances) sudden weakening of pulse, without slowing; after the convulsive movement the pulse regains its intensity. The somnambule, who, according to all appearances, knew not the localities I made her traverse and visit, though she was of Franche Comté and Haute-Saône, betakes herself to the village where I was born, the name of which I withhold from her, and which she names of her own accord. But in passing by way of Pontarlier she gives the name of that town; tells the direction in which lies Les Fourgs—the village in question; describes the road leading thither from the Department highway; assigns the position of the church outside the village, and gives almost the number of my father's house; adds remarkably correct particulars about my mother, the sequels of her lying-in, her ailment, the treatment, her death. But she is mistaken as to my age at the time of the death, and on the make-up of the family. She hits it exactly with regard to sundry details of the life of my father and my mother, and is mistaken as to some others. She describes with great precision the features of the country as one observes them in following the path leading from the village to the hamlet of La Beuffarde; makes two mistakes with regard to the house I used to live in; then describes its parts precisely; is mistaken as to the cause of the ruin of a neighboring house. She gives correct details about my early years; follows me elsewhither; is only half-way mistaken with respect to my situation at Pontarlier from 1815 to 1819; is more exact as to my life and occupation at Besançon; but her intuition of the remainder of my life is a little more obscure, though a pretty large number of the particulars are true."

In this narrative we have a somnambulic dream, fed by verbal suggestions, but also by communication of recollections, especially recollections of early childhood, which are wont to be vivid.

Mr. Tissot's somnambule, as also Mr. Joly's, was deaf to impressions not proceeding from the person with whom she was in rapport.

Mr. Tissot presents his manner of making notes as a model. But

[1] J. Tissot, "L'Imagination, ses Bienfaits et ses Égarements," p. 119. Paris, 1860.

it is far from being satisfactory. He has noted all the errors of the somnambule, but that is not enough. The entire dialogue must be noted. Hence I prefer General Noizet's narrative.

General Noizet, author of several philosophical works, and whose volume on somnambulism was praised at the Academy of Sciences by Flourens, recounts the following fact:

10. "I reached my friend's place before the magnetizer and his somnambule, and the master of the house told us that among the extraordinary powers she was credited with was, that she could tell what a person with whom she was put in rapport had been doing throughout the day. Now, on that very day it chanced that I had done something quite out of the common—I had gone to the Hôtel des Invalides with the Duke de Montpensier, to show him the gallery of relief-plans of the fortifications. I proposed to test on myself the somnambule's power, and this proposition was accepted by my two friends. The somnambule having arrived and having been endormed, I forthwith put myself in rapport with her, and asked if she was able to *see* what I had been doing that day. After some details of little consequence, and obtained with difficulty, as to how I had passed the morning, I asked whither I had gone for breakfast. She answered, without much hesitation, 'To the Tuileries.' That might mean a simple stroll thither, so I persisted and asked at what point I had entered. 'By the wicket on the quay hard by the Pont-Royal.' 'And then?' 'You went up into the château.' 'By which steps, the middle ones?' 'No; by those at the corner, near the wicket.' Here she lost herself among the different sets of steps—and well she might, for there are many of them. Finally she set me down in a large hall where some officers were. It was a reception hall on the ground floor. 'You waited,' said she to me. 'And then?' 'A tall young man came and spoke to you.' 'Who was that young man?' 'I do not know.' 'Try hard to find out.' 'Oh, it is the King's son.' 'Which?' 'I do not know.' (I tell her it was the Duke de Montpensier.) 'Afterward?' 'You entered a coach.' 'Alone?' 'No; with the prince.' 'Where was I placed?' 'In the rear, to the left of him.' 'Were we two alone in the coach?' 'No; there was, further, in front, a stout gentleman?' 'Who was that gentleman?' 'I do not know.' 'Try.' (After reflecting) ''Twas the King.' 'How,' said I, 'I on the rear seat and the King on the front? You see that is not reasonable.' 'I can't say; I do not know that gentleman.' 'Well, it was the Prince's aide-de-camp.' 'I do not know him.' 'Where did we go?' 'Along the riverside.' 'And then?' 'You entered a large château.' 'What château?' 'I do not know; there are trees before you come to it.' 'Take a good look at it, you must know it.' 'No; I don't know.' (I drop this question and tell her to continue.) 'You were in a large hall.' (Here she gives me an *imaginative* description of the hall, where she see stars glittering on a white ground.) At last she said to me: 'There were long tables.' 'And what was on the tables?' 'It was not high nor was it entirely flat.' (I could not bring her to tell me that it was relief-plans—things that she, no doubt, had never seen.) 'What did we do then, at those tables?' 'You got on a bench, and with a long rod pointed out something?' (This remarkable specification was perfectly exact.) At last she had us in the coach again and away. I then said to her: 'But just look back; you must recognize the place

we are leaving.' 'Ah!' she said, as though astonished and confused, ''tis the Hôtel des Invalides.' She said, furthermore, that the Prince quitted me at the door, which was the fact.

"Though familiar with the phenomena of somnambulism, this scene nevertheless impressed me much, and I could not reasonably attribute to any cause save the faculty of reading my thoughts or of deciphering impressions still existing in my brain, the kind of divination exhibited by the somnambule. That is the only explanation I can give even to-day."

This observation is curious, indeed, in that it proves:

a. That till the moment when the General had fixed his attention on some detail of his recollections, the somnambule divined nothing.

b. That sometimes she spoke according to verbal suggestions made by the General, and that then either she wandered abroad in conjecture, or else complemented these verbal suggestions with details mentally transmitted.

c. That she "saw" best the details that had left the most vivid traces on the mind of the General.

d. That the traces partially transmitted were completed little by little, till they formed a more distinct image (the Invalides).

e. That sometimes reflective conjecture failed completely, and then the somnambule guided herself by images passing spontaneously through her mind (the King).

11. "Professor Barrett, of Edinburgh, tells of a young Irishwoman who, though she never had been away from her native village, was able to describe Regent Street, London, which street he was thinking of when he magnetized her. From this fact and from other facts like it, Professor Barrett concludes that any idea upon which the operator concentrates his thoughts produces its like in the mind of the magnetized subject."[1]

12. Mr. Ch. Richet has recently collected many observations of this kind (not yet published). The subject, when questioned by the operator, describes a chamber, a house, etc., according to the magnetizer's recollections. These observations, made with exactness, possess a special interest, for they may help us to determine the rôle of *unconscious recollections* in the act of transmission. We may in this way decide whether, and in what proportion, the knowledge one possesses, but which at the moment is not present in the mind, can be transmitted to the subject. All that is needed for attaining this object is carefully to note and describe in detail the operator's mental state.

13. Mr. William Gregory, ex-Professor of Chemistry in the Uni-

[1] I quote the passage from P. Despine (*op. cit.*),only correcting the name of the operator from *Bennet* (as given by Dr. Despine) to *Barrett*. Prof. W. F. Barrett, no doubt, is meant, for this experiment is described in an article by him "On Some Phenomena Associated with Abnormal Conditions of Mind," published in the "Proc. Soc. Psych. Res.," p. 238. July, 1883.—*Author's note.*

versity of Edinburgh, quotes a similar case, but I have not his book at hand.[1]

14. The Count de Maricourt,[2] from whom we have already quoted a few lines, gives the following narrative:

"It has often happened to me to be staggered and nonplussed by the clairvoyance of somnambules, who told of impressions or divined sentiments that I could have wished to keep secret from them. As I lived in association with these persons, the fact may be accounted for by the habitual community of thought existing between us. To put aside this cause of illusion, I tried an experiment upon a person entirely unknown to me. A professional magnetizer was at the time exhibiting in Paris a certain somnambule, about whose performances marvelous stories were told. She knew the past, the present and the future, understood all languages, and above all divined the most secret thoughts. The seances were held in a large hall on the boulevards. You had only to give her your hand and concentrate your thought upon any object whatever, and she would tell you, following your thought, what the object was. I saw several gentlemen interrogate her thus tacitly. One of them thought of a murder, of a duel he had witnessed; another made her a witness of some battle scene, of a shipwreck, or of a fire. The somnambule's descriptions seemed fully to convince her patrons. As I did not believe in the supernatural, I did not wish to be fooled by jugglers. These gentlemen, who were unknown to me, might easily enough be accomplices. 'It is not necessary (said the Barnum of the establishment) to entertain the somnambule with tales of horror and disaster only. On the contrary, I should say you fatigue her by occasioning painful emotions.'

"I, too, wished to experiment in my turn; in accordance with the advice of the manager, I called up a pleasant memory inwardly, going back to a remote place in the country, and to a time some few years before."

The author here recounts the whole story of a feast in which the dominant figure is a drunken man, with red nose and a very comical face, whom he describes in detail.

"I said not a word (he continues) to the somnambule, but to this vision of the past I strove to give, in my mind, the luminous distinctness of a photograph. 'Oh, what a ridiculous phiz! (exclaimed the seeress after a few moments). What a phiz, what a phiz, my God!' Her almost convulsive laugh had in it something so infectious that the whole company shared her jollity.

"This time I had to confess myself entirely convinced. To the faculty—unexplainable by the play of the organism—of seeing thus into the minds of others must be attributed the alleged facts of somnambulic polyglotism."

This experiment is not quite conclusive, for jollity being the order of the day after the magnetizer's speech, the somnambule divined only the mental image of a phiz. But granting this not to have been

[1] Gregory, "Letters on Mesmerism and Clairvoyance," Edinburgh, 1852; Morin, *op. cit.*, p. 168.

[2] R. Comte de Maricourt, "Souvenirs d'un Magnétiseur," p. 96 *et seq.* Paris, 1884.

pure chance, the experiment is instructive in this, that the humorous, comic element, being transmitted to the somnambule and producing laughter, hindered the transmission of all the objective images that were in the mind of the Count.

Another experiment that I find in the same book is more convincing:

15. "I was walking with a patient whom I had endormed beforehand. [There is nothing unusual in this walk. In active somnambulism the subject presents all the appearances of a waking person. If the somnambulism, however, is not deep enough, the subject may be awakened by a current of air. In other cases you might throw the subject into water or into a fire without awakening him.] She was paralyzed in the legs and could walk only in the magnetic sleep. [This, too, is seen often enough in hysteric paralysis.] As we passed in front of a field, the owner of which I knew, I asked her *to tell me his name*, and at the same time pronounced the name inwardly; I had some difficulty in obtaining a satisfactory reply. [Observe, the patient was in an active polyideic state.] The subject declared that she could not tell it to me; I insisted, and the name was pronounced as I wished. It is, you see, a hard job (*fait brutal*), for the subject has to see what you think and what she cannot guess. No more striking instance of thought-reading can, I think, be found" (p. 123).

16. Dr. Puel, author of a memoir on catalepsy that was "crowned" by the Academy, also made one of his cataleptics divine words he thought of; only he made the task light by indicating the terminations. He would say to the patient: "Tell me the word I am thinking of; it rhymes with——" (clairvoyance, for example), and the subject gave it without hesitation.[1]

17. Dr. Comet, editor of medical journals and a distinguished writer, was a thorough unbeliever in somnambulism, and had often amused his readers by ridiculing the wonders of lucidity as reported by magnetizers. In 1839, his wife, having fallen ill, had a fit of *natural somnambulism*, and became lucid. Mr. Comet (whose testimony has the more weight, inasmuch as it dealt with facts that he had considered impossible) sent to the Academy of Medicine a detailed report and published the same in the journal *L'Hygie*. To mention but two of Mrs. Comet's feats, she would describe every little object held in the closed hand and divined thoughts *that related to her*.

I pass over other feats that have to do with another question, that of clairvoyance, that is, when the subject sees or divines things that cannot be known to the persons around her. After quoting the description of these curious facts as found in Dr. Comet's "Report," another physician, Mr. Frappart, adds: "Surely it must have cost its author dear, for but the other day he was one of the most determined opponents of magnetism." But Mr. Comet "did not go there by four roads," and here is what he himself wrote in his "Report:"

"The unfortunate ailment of my wife carries with it a consolation, for it will bring to unappealable judgment a question that has been the subject of much discussion in this Academy and in the press, wherein I have taken an active part—I speak of the lucidity and

[1] A. S. Morin, "Du Magnétisme et des Sciences Occultes," p. 177. Paris, 1860.

clairvoyance of somnambules and the wonderful things they do. Three months ago I myself did not believe them, and to-day I regret my having characterized them publicly as fraudulent devices and catchpenny tricks."

There is a piece of advice for hypnotizers who are doing the same thing to-day!

But as for the hope that Dr. Comet fostered, in the belief that the Academy would profit by this occasion and decide, as the highest court, a question that so profoundly concerns the progress of science —what an illusion!

The Academy could not refuse to name a commission that was asked for by an esteemed member. The commission even went twice to visit Mrs. Comet; but after remarking that the case had some extraordinary features, in dealing with which they might compromise either their sagacity or their renown, they hesitated about going on.

"I notified all of them this morning," wrote Mr. Comet, "and I count upon them for this evening"—the business being to verify a prediction made by the patient. "The fact is of sufficient interest to science and humanity for them to take cognizance of it." "Be not deluded," answered Dr. Frappart, "not one of them will come, either to-night or to-morrow, or later, for a man carefully holds aloof from the truth that hurts him."

In fact, no member of the commission went.[1]

18. A well-known physicist-prestigiator, Mr. Robert-Houdin, took a greater interest in these questions. We have already mentioned his imitating second-sight and thought-transmission, by means of a very ingenious trick. At the outset he was very incredulous about somnambulism. Nay, accustomed as he was to perform wonderful feats, he made light of marvels, and believed he held the secret of them all; and he, too, regarded the extraordinary performances of lucid somnambules as clever tricks. In many towns where somnambules had been successful, he amused himself by counterfeiting their doings, and even surpassing them. Mr. de Mirville, the famous demonologist, who, in his system, has need of somnambulism, thereby to do honor to the spirits infernal, conceived the ambitious project of converting so doughty an adversary. With good reason he judged that should he succeed in proving to Robert-Houdin that lucidity belongs to a class of things entirely foreign to his studies and his practice, the testimony of so expert a judge would be of great service to the cause of magnetism. So he took him to see the somnambule Alexis. Mr. de Mirville, in his book on "Spirits," describes the scene.

Mr. Morin, from whom I borrow this passage, and who wrote a *spirituel* but skeptical book on magnetism, declares that Robert-Houdin assured him of the exactitude of Mr. de Mirville's narrative.

"I was amazed, confounded (says the prestigiator). Here was neither trick nor jugglery. I was witness of the exercise of a higher,

[1] Dr. Frappart, "Lettres sur le Magnétisme," 1839, 1840; Dr. Comet, "La Vérité aux Médecins," 1869; Dr. Charpignon, "Physiologie," etc., p. 116, 1848; Morin, "Du Magnétisme," p. 176, 1860.

an inconceivable faculty whereof I had not the slightest notion, and in which I would have refused to believe, had not the facts come under my own eyes. So great was my emotion that the perspiration streamed down my face." With other experiments he mentions the following:

19. "Alexis, seizing the hands of my wife, who accompanied me, spoke to her about past occurrences, and in particular about the very painful loss of one of our children; all the circumstances were recounted accurately." [In this case, the somnambule read in the mind of Mrs. Houdin her recollections and her sentiments, which were more or less vivid in her consciousness.]

Another feat of the same somnambule simulates vision and clairvoyance at the same time, as in the case last mentioned, by transmission of recollections.

20. "We had with us a physician, a strong unbeliever, Dr. Chomel, who, desiring also to study the matter for himself, presented to Alexis a little box. The somnambule felt of it without opening it, and said, 'It is a medal; it was given you under rather singular circumstances. You were then a poor student, living at Lyons in an attic. A workman to whom you had rendered some services found this medal among refuse, and thinking it might be of some interest to you, climbed your six flights of stairs to offer it to you.' This was all true. Certainly here are facts that one can neither guess not hit on by chance. The doctor shared our admiration for the feat. I gave to Mr. de Mirville the certificate he asked of me, stating that the facts I had witnessed surpassed all that can be done by sleight-of-hand."

Another quotation from the same author will be found interesting for the very reason that it mentions some mistakes made by the somnambule:

19. "Some months after, I went a second time to consult Alexis. I did not find him as lucid as at first. I was specially impressed by one feature. I presented to him a letter I had just received, and which had not yet been opened. [But Mr. Houdin *knew* whom it was from.] It bore the Boulogne post-mark. Alexis told me it had come from England, which was true, and gave me a *pretty correct* description of the writer. He made a mistake in saying he was a book-seller; I took him up, and then he said he saw him in a room filled with books and like a book-seller's shop; and such in fact was the appearance of the sitting-room of my correspondent."[1]

When we recall a person to mind, we automatically (*machinalement*) recall also his surroundings, the background on which his silhouette is limned by memory; and doubtless it is this fleeting image that was communicated to the somnambule and led him to say, *conjecturally*, that the writer of the letter was a book-seller. Note again, that the seer did not tell Mr. Houdin what was in the letter: that was a detail of which Houdin himself was ignorant.

Facts like these last are usually classed as feats of clairvoyance, or

[1] A. S. Morin, *op. cit.*, p. 180.

are confounded with others which, if they are correctly reported, seem really to exhibit a faculty different from the one we are considering here.

And, strange to say, there are in the history of magnetism, even though we restrict ourselves to observations made by scientific men, more facts of clairvoyance, relating in particular to questions of the health of patients, than there are facts of mental suggestion properly so-called. It is true that in many cases of somnambulic consultation, we must absolutely presuppose the *mental influence of the physician*, unless we are willing to accept explanations more extraordinary still, or totally inadequate.

Baragnon distinguishes mental transmission from lucidity; he is right, for what is called "clairvoyance" (I do not mean to discuss here the value of that "faculty," not having studied it sufficiently) presupposes a state *rather more polyideic* than the one that favors passive transmission. Lafontaine, too, had too much experience not to have noticed that the transmission of sensations of thought and of will does not imply lucidity. He even observes that often they who consult somnambules do in reality consult themselves, the somnambule merely reproducing their thoughts. But Baragnon is more explicit. "There may be," says he, "thought-transference without clairvoyance, just as there may be clairvoyance without thought-transference: the two phenomena are independent." He names as conditions favoring thought-transference these:

1. "A close sympathy of the magnetizer with the subject.

2. "A sleep cheerful (*gai*), free; highly developed magnetic vision.

3. "Transmission of sensations as a basis."

As for the first condition, nothing more needs to be said. Plainly, *sympathism* is more facile where *sympathy* already exists.

With regard to the second, I am a little surprised to find that the sleep must be *cheerful* and *free*, for to me such sleep seems less favorable to true transmission, though it is highly favorable to divination by conjecture.[1]

By "magnetic vision" Baragnon understands the faculty that many somnambules possess of making their way about and finding their bearings though their eyes be closed, even in places unfamiliar to them, or in the dark. It is far less exact in details than ordinary vision, but, according to this author, it becomes very accurate when an organism is put in rapport with the somnambule.

[1] "Cheerful and free sleep" is not a happy phrase, and does not render with precision the French *sommeil gai et libre*. The meaning of "gay," "free" sleep, is perhaps best obtained by looking at its opposite, namely, magnetic sleep in which the somnambule is more or less *inert* mentally, say, *without initiative*, and is *restricted* in his psychic action. In other words, "gay, free," = *polyideic*.—*Translator*.

We must not be too ready to ridicule this *magnetic vision.* I cannot analyze here the question of *vision with closed eyes,* which, indeed, I have studied but little, and I do not yet admit the existence of such faculty. I believe that in the cases in which it has been supposed by competent observers to exist, for example, the case reported by the Academy Commission, it may be regarded as an exaltation of vision, that is to say, *vision through the eyelids.* But what Baragnon calls "magnetic vision" is a complex phenomenon, sometimes independent of the visual organs—rather an exaltation of *touch* or more probably an *elective and limited exaltation* of all the senses, sometimes of those of touch and hearing, sometimes of sight and smell, etc. That is what I mean by elective, or specificated hyperæsthesia.

When the magnetic sleep is thorough, the subject is insensible, deaf, and blind to all that takes place outside of the magnetic "rapport." But in turn his senses are hyperæsthesic with respect to the magnetizer, or of any object upon which he fixes his attention. The apparent contradiction must not shock us. The senses are unchanged, but the state of the *brain* may modify their action in the direction of *plus* or of *minus.* In the first place, the same quantity of nervous energy may, instead of being expended on all the senses, be concentrated upon one at the expense of the rest; then, in the same sense (touch in particular), it may be concentrated in one region, in a single point, at the expense of the rest (the hysterogenic zones belong to this class); finally, this displacement may be still further specificated by a *brain-adjustment.* A mother that is not awakened by a loud knocking at night, is up with a leap at the faintest cry of her babe, because her brain is adjusted for that kind of impressions only. There is an *unconscious attention* that watches without interfering with sleep. One forms the intention of awaking at 5 o'clock in the morning, and at the stroke of five awakes; and so on.

Somnambulism shows us magnified what is exhibited on a small scale every day of our lives. The magnetizer is for his subject like the figures at the opera that are illumined by an electric light. He alone is visible, around him all is darkness; but he it is that holds the reflector, and he can project the light whither he will.

The somnambule "sees" with closed eyes his magnetizer, or at least translates by the term "vision" *all* his concentrated and exalted sensations, which come from the magnetizer. He feels his presence, knows whether he is to the right or the left, whether he is walking or motionless; to a certain extent, he senses even his gestures; all this through perception of air-movements, of warmth, of cutaneous odor, of noises made, of tones of voice, etc.; and these impressions being by habitude associated with visual images, the somnambule translates them into terms of vision.

"Magnetic vision," in this sense, is, of course, a favorable condition

for mental communications; yet it implies a theory of divination rather than a theory of direct transmission. Baragnon leaves the question undecided.

Finally, the third condition, too, is consistent with physiology. Thoughts are only sensations cerebralized (excuse the word !).[1]

Not only are sensations the sole springs of ideas in their primitive form, but every fully elaborated idea, so far forth as it is active, is accompanied by unmodified sensations,[2] unconscious for the most part, but which sustain the consciousness. So, too, it is accompanied by the inchoate reflex movements proper to it (Sietschenoff), and Campanella, perhaps, was in the right when he said that if he could imitate precisely the attitude[3] of a man that is thinking of anything, he could at once divine his thought.

"There is no doubt," says Baragnon, "but that transmission of sensations has much to do with thought-transference." He holds that the reciprocal sensations of two organisms, in the state of erethism that *conditions* that phenomenon, *awaken* in the mind the same thoughts, precisely as in ordinary perception, in which the words uttered enable us to know the thoughts.

In that sense, properly speaking, there would be no transmission of thought, but only of sensations. The theory is tenable, but not in every instance, for mental suggestion may exist without transmission of sensations, at least without perceptible transmission.

The following fact would seem to have supplied a basis for the views of Baragnon:

"I was smoking quietly in company with some gentlemen in an apartment adjoining a parlor where that evening I had made some experiments, when the request was made unexpectedly that I should endorm from a distance my subject, who had remained in the parlor with the ladies; I did so without knowing that he was dancing. The fluid came upon him like a lightning-stroke, and with the sleep he had a crisis. I was summoned. The somnambule was surrounded by a ring of spectators standing so close that I had difficulty in getting through. 'Hey! Get out of there, if you want to have him recover,' said I, gruffly, to a young officer that kept me back, not knowing me; for I was thinking only of my patient, and had put politeness in quarantine. The crisis was checked straightway. I let the subject sleep for a few minutes in quiet, and thought of everything but the young officer. The latter after a few moments came up to me, no

[1] But the term admits of no apology! Moreover, it is unnecessary, for a perfectly legitimate one might have been coined to express the idea, to wit, *'encephalized.*—*Translator.*

[2] *Sensations brutes* = sensations "in the raw state."—*Translator.*

[3] The word appears to be used in a larger sense than attaches to it commonly in English. Doubtless it denotes here *the whole* nervo-muscular action of the man, internal no less than external, *not* merely his pose, the direction of his eyes, etc.; not simply his outward action and bearing, as a good mimic might render the same.—*Translator.*

doubt to demand an explanation of my rudeness, my subject rose to his feet, went toward the officer, stopped him, took hold of his hands, and said: 'You are offended He is in the wrong, excuse him, he is quick-tempered, but he is kindly.' On learning what was the matter, I hastened to offer my apologies, which were courteously accepted. I then questioned myself as to the purport of this phenomenon. Nobody, in the confusion of the moment, had heard me speak to the officer I had no recollection of having said a word to him. Somnambules hear nobody but their magnetizer, and my subject was in the crisis."[1]

The author gives the story without comment, but comment is necessary.

1. We have here a pretty clear case of will-action from a distance. The crisis came on in consequence of a collision between the subject's activity (dancing) and the magnetizer's unexpected action. This action is at present unexplained, unless we are content with the explanation given by Baragnon—fluid-projection. But we pass that by; we will return to it later.

2. The magnetizer could not transmit his sensations, for he took no notice of anything, being occupied with his patient. The only supposition would be that he had unconscious sensations, and that they were transmitted unconsciously—a supposition impossible to verify.

3. But what may be considered certain is, that the somnambule heard his magnetizer when the latter said to the officer "Hey, get out," etc. His attention was attracted, and it is probable that the officer muttered some words that the subject heard likewise. He divined the situation, his attention remained fixed on the impressions coming from the officer, and sympathy determined his course.

It is true that, as a rule, somnambules do not hear strangers, nor even their magnetizer when he addresses his speech to other persons; but in this instance the voice indicated the coming of the magnetizer, and when that is the case it is often heard. Then, recall what we have said above concerning unconscious sensations, not perceived directly, but which enter the brain, there to manifest themselves afterward at a favorable moment.

Consequently, this observation does not even prove the transmission of sensations.

We have already quoted Dr. Teste, who believed that he could hold a mental conversation with his somnambule, as Madame Guyon used to converse with her confessor. Puységur mentions several facts of this kind, among others the feat of a cataleptic who, *being deaf*, answered for some moments very detailed questions put mentally "without words and without any expression of the face-muscles." He quotes the answers word for word.

General Noizet gives the following narrative:

[1] Baragnon, *op. cit.*, pp. 137, 301.

"One of my friends, a young physician, employed in a Paris infirmary, did not believe in the surprising facts of somnambulism. I induced him to make experiments on one of his patients. He followed my advice, and soon he had a somnambule. He had heard that these singular beings can answer questions put to them mentally. He questioned his somnambule in this way on behalf of another woman that was present, to whom he did not wish his question to be known, and, as luck would have it, the somnambule answered with such correctness that he did not easily recover from the emotion caused by so extraordinary a feat."[1]

I never have observed anything of this sort, save for a moment with regard to a few detached questions. But there once was a physician who declared that this phenomenon was of constant occurrence with a patient of his. This was Dr. Barrier, of Privas, who, in a memoir addressed to Cuvier and to the Academy, in 1835, mentions the following facts, observed in the case of a patient, Euphrasia Bonneau :

1. "Complete insensibility, except at the epigastrium, where life is concentrated." (This often is the case with magnetized hysteric subjects. "Life concentrated at the epigastrium" means simply that the epigastrium is the only sensitive part, and that only through that part of the body "rapport" could be maintained. We find similar facts in Petetin, Frank and others.)

2. "The gift of divining the thoughts of a person who comes into rapport with her: so pronounced is this faculty, that Euphrasia *holds a conversation in which the interlocutor speaks mentally only.*"

3. "Production of very remarkable electro-magnetic phenomena."

4. "Abolition of sight, taste and smell in the organs of those senses, and their transfer to the epigastrium." (We need not consider this phenomenon here; it can be studied in Petetin, Frank, Teste and Despine.)

5. "Prevision of future events with regard to her ailment."

(There was a good deal of amusement recently at the Academy of Sciences *apropos* of a communication of this kind. The faculty nevertheless exists, and is in nowise extraordinary. An hysterepileptic patient sometimes foresees a paroxysm, knowing by the *aura hysterica* that it is coming on; a magnetized hysteriac, whose whole attention is concentrated inwardly, may foresee it several days in advance. Finally, it is to be observed that the unconscious sometimes *foresees* what it is itself going to produce.)

6. "Appreciation of the value of remedies proposed; *feeling others' sufferings.*"

7. "Strong inclination to act the part of prophetess."[2]

I quote this communication only as part of the record.

[1] Noizet, "Mémoire sur le Somnambulisme," p. 127. Paris, 1854.

[2] I have not been able to obtain this memoir; I merely find it mentioned by Charpignon ("Phys., Méd. et Mét., p. 397).

CHAPTER V

DIRECT WILL-TRANSMISSION.

WE come now to will-transmission. I begin with a narrative by a very good observer, now almost utterly forgotten. Fournel[1] tells us of a somnambule whom he ordered to take a hat that lay on a table in the middle of his sitting-room, and to go and put it on the head of one of the company.

"This will (he writes) I did not express in speech, but only by a sign, which traced the lines I wanted him to go over, and which ended at the hat. The somnambule, *whose eyes were bandaged*, rose from his chair, followed the direction indicated by my finger, advanced toward the table, took the hat from among several objects, and went and put it on the head of the person indicated."[2]

It is to be remarked that the gestures of the magnetizer help the experiment, even when they are not seen by the subject. Sundry agents contribute to this result. 1. Air-currents, often very clearly perceptible at a distance. 2. Auditive impressions accompanying the gestures. 3. Attractions, very active in some subjects. 4. The mental concentration itself of the operator, which is much facilitated by his mimetic gestures.

Fournel's work appeared in 1785, that is, a year after Puységur's classic memoir. I have begun with this little observation of Fournel's because, though it is not altogether demonstrative with regard to mental suggestion, it yet presents the most usual type of experiments in *will-transmission* as ordinarily practiced.

But we must not forget that Puységur was the first to propose this kind of researches. He it was that first proclaimed the reality of the fact and met the cavils of his contemporaries.

One often wonders that certain studious observers should have retained the term "*magnetic* sleep," given by Mesmer and Puységur to a certain form of artificial somnambulism, confounded nowadays with hypnosis. The passages I am about to quote will give the reason for so denominating it, and will show a close relation between it and will-transmission. The analogies that Puységur believes he finds subsisting between certain electrical and magnetic phenomena, and the aptitudes of somnambules, may seem to us in these days inexact and superficial; but neither must it be forgotten that even he considers them only as analogies, and not as proofs of identity.

[1] Fournel, the advocate, was the author of three remarkable writings: "Essai sur les Probabilités du Somnambulisme," Amsterdam and Paris, 1785; "Mémoire pour le Docteur Vernier," 1785—a defense of Dr. Vernier whose name was dropped from the rolls of the Faculty for having practiced magnetism; and "Remontrance des Malades," etc., 1785.

[2] "Ess. sur les Prob.," p. 48.

The following narrative has reference to an epileptic (probably hysterepileptic) girl, of whom the author speaks in his second "Mémoire:"

"This girl, in the somnambulic state, showed the utmost *magnetic mobility;* and as, barring her nervous disorder, she was of very strong constitution, I had no fear lest I should injure her health by subjecting her to all the experiments for which she was fitted. Of all those who at the time came to my house to satisfy their curiosity, there must doubtless be still many who will recall the hours they passed there, and the details I am about to enter upon.

"Before presenting Magdeleine before the company, I always began by announcing to the spectators not only what I was about to perform, but also what each one might perform to convince himself. 'The girl once in the somnambulic state,' I used to say to all, 'will present to you all the phenomena of electricity and of the magnet; comparable at first in all respects to an insulated body charged with *electric fluid*, she will be in communication with me alone, so that to touch her without risk of doing her hurt, and to make yourself heard by her, I must put you in rapport with her. Then, regardless of rest or of motion, she will obey all the intimations of your will, as readily as a magnetic needle obeys the iron held out to it.'

"As can be understood, an announcement so extraordinary prepared the minds of the majority of the audience for an illusive performance, rather than for a real exhibition of unwonted powers; but my subject was so well fitted to re-assure the audience by the passive state of all her sensations, that I felt sure I should, by her means, triumph over all uncertainties and over all the cavils of incredulity.

"Magdeleine having entered, I performed upon her what I used to hear called, ironically, 'the great work,' or 'the mystery.' In two or three minutes, though no movement, no change, could be observed in her, she closed her eyes and was in the electro-magnetic state. I then invited the two or three persons named in advance by the company, to begin the experiments. If one touched the arm, or even only the apron of the girl, she was seen to quiver and to suffer; a bit of paper laid unawares upon her head weighed her down as though she were bearing a heavy burden hard to sustain. I have to say that at each shock (*commotion*) thus given her (for such in truth it was), I made haste by my touch to put her nerves at rest again, and the mischief done her was at once repaired. . . . If anyone spoke to her, she made no reply, and whatever noise might be made at a little distance from her, she seemed to be insensible to it. I then made a sign, for I did not speak, fearing lest people might suspect some understanding between the girl and me—I proposed, I say, to somebody to give me his hand; immediately she, grown indifferent to the approach [of the stranger], answered him as she would have done in her natural state. Eight or ten persons joined hands, and provided they were in communication with me, the last, or the one nearest to her, repeated the experiments with the same success. When I thought I had proved sufficiently the analogy of the phenomena she presented, with those of electricity, I proceeded to the experiments designed to prove the same analogy with the magnet. To this end, I took a position face to face with her, and, without speaking, made her rise from her chair, and, by a sign, or even without any sign, with the hand (which,

indeed, she could not have seen, for her eyes were shut), I directed her to a given part of the room, or to a given chair in which I willed her to sit; I then, still mentally, made her touch, take up, and fetch me any object; but, because, seeing that she did not act save by my direction, people might think with some show of reason, that I had an understanding with her, I used to say to the spectators:

"'I have made the experiments you have just seen, only to show you in what way you are to act in order to repeat them yourselves: the one among you with whom I am about to put this young lady in harmony, will make her obey, as I have done, all the indications he may have in his mind. I ask of you one thing only, namely, that once your will is decided, it shall remain firm and constant, and shall not again change in direction. Imagine some one that never has seen a mariner's compass, to whom is given an iron rod, with the remark that by means of the same he can guide the needle at his will; if every time he saw it going in one direction he should forthwith move the tip of the iron rod back again, you know that he would then produce only an oscillation, and might thence draw the conclusions most favorable to his ignorance or his prejudices. It were worse still if, his self-opinionatedness revolting at the sort of doggedness with which the needle followed his indications, he should jump from one pole straight to the other, for then the needle, resuming of necessity its first position, would make him dead-set in his incredulity. You, gentlemen, will stand in the same relation toward this young woman as the iron rod toward the needle; it will, therefore, be your fault, not hers, if you see her for one moment vacillate in following the guidance of your will.'

"I cannot but laugh even now when I recall the little eagerness shown to make this last and conclusive experiment: if people had shown indifference toward trying the experiment of electrical communications, they refused to put themselves to the test in this. True, one had to begin with an act of faith, a thing always hard to do, and then to behave consistently with it, perhaps a more difficult thing still. Yet there was never a seance at which seven or eight persons at least did not make trial of their will-power, or in which that did not happen which I have already described. If a person fixed his thoughts fast upon an object, and designated it with the hand or only with the eyes, the girl went to that object and touched it or took it in hand without hesitating; but, if a person through want of confidence or through timidity ceased to fix his thought, the girl would follow the oscillations of the man's mind; if the thought was turned in another direction, in the hope of putting her out, she was seen to vacillate, and then to stop short and stand still. A weak will, one but little set upon a purpose, was with respect to her what the iron rod is with respect to the needle when, being at too great a distance, it receives therefrom too slight an influence.

"Though, when the girl was in the magnetic state, her eyes were always shut, and she could not open them, nevertheless, in order to do away with all suspicion of trickery or subterfuge on her part, I used, whenever anybody desired it, to put a thick bandage over her eyes, a thing equally indifferent to her and to myself, and the results of her magnetic mobility were the same.

"How many persons on whose esteem I had some claim, and how many others whom, in view of the respect they enjoyed in the world, it would have been an honor to me to convince of the reality of the

phenomena, nevertheless left my house, not only not believing in what they had seen, and what they had themselves performed, but with more than a doubt of my good faith! That I should appear in their eyes, if not exactly as a sleight-of-hand trickster, at least as a deluded enthusiast, is still a painful thought for me. But how great is the power of prejudice, if the purest truth, presented by the being who is least interested in making it known, is unable to overthrow its baleful prestige!

"Though I have made it a law for myself not to name any of the persons who for two months came in succession to take part in, and to be witnesses of my experiments, still I think I may, without indiscretion, name one of the more notable. The Baron de Bezenval wrote to me to express the desire that I would go on a certain evening with my somnambule to the house of Mr. Mitonard, a well-known pharmacist and an able chemist. There was a numerous company present, but very few of the people were known to me. After having called into play, with my wonted good faith, the electro-magnetic powers of Magdeleine, and observed very clearly that the company had little faith in their reality, I begged Mr. Mitonard himself for a moment kindly to suppose that what I wished to persuade him was true. 'In any event,' said I to him, 'there would be some mystery in what I am proposing to you; and though the facts you have witnessed should be referable to a different cause from the one I assign, it will still be interesting to you, even should you be unable to tell why, to see this girl act in accordance with your thoughts alone; but, give your thoughts a fixed direction, and will strongly the execution of them.' Mr. Mitonard having agreed to this, made known to a few persons what he intended mentally to demand of the somnambule; and this preliminary, which assured me of the fixedness of his thoughts in a definite direction, left in my mind no doubt as to the success of the experiment. So, having put the young woman in communication with him, I left her entirely at his disposal, and withdrew to a corner of the room. Mr. Mitonard, after having made her walk about and sit down, and take different objects in hand, as well from the mantelpiece as from the table, acts which, in view of the promptitude with which she carried out his intentions, were to me proof that his thoughts were strongly fixed, now stopped, and standing straight before her, without making any movement whatever, remained in an attitude of deep thought. Instantly the somnambule moves her hand toward one of his coat-pockets, thrusts it into the bottom, and takes out three small screws that he had put there, and which he had had the intention that she should go to the pocket for and take out of it. . . Mr. Mitonard's astonishment, and the assurance everyone had of the execution of his thought, for a moment overcame their incredulity; but soon, *How is it done?* and *That is incredible*, and *The thing is impossible*, put a stop, I fancy, to the current of the reflections that each one must have been making, for I have not heard of them since.

"From this narrative it is seen that I did my best to open the eyes of educated men of all classes and all conditions, to the interesting discovery of animal magnetism; and my confessed incapacity to explain to them all its phenomena ought not, I think, to be to them a reason for denying its reality."[1]

[1] See p. 11 of the "Suite de Mémoires pour servir à l'Histoire du Magnétisme Animal."

Let us now consider a few more recent observations :

"It was (says Lafontaine) at one of the seances held at the house of the learned and very incredulous Dr. Bretonneau, that I was so fortunate as to see and hear Béranger, our celebrated balladist. Béranger having witnessed several experiments on thought-transference, wished to make some himself, in order, as he said, to convince the doctor, who could not mistrust him. After some directions given by me, he took the somnambule's hand, telling her to do what he would order her mentally. He exerted such will-force in the experiment that his other hand caused the table on which it rested to tremble. Soon the somnambule was seen to rise, go toward Dr. Bretonneau, take him by the hand, and, in spite of his resistance, lead him to Béranger, who declared that such had been his mental order."[1]

"At another seance the name of a lady was written on a piece of paper ; the paper was passed to me, and immediately the somnambule was seen to rise, take a bouquet, and carry it to the lady indicated."[2]

An eminent physiologist, Mr. H. Beaunis, Professor at the Faculty of Nancy, said recently : "I have never been able to find in the subjects I have observed, the wondrous phenomena spoken of by some magnetizers. Whenever the suggestion I wanted to produce was simply *thought*, and not expressed in one way or another, it never has been carried out. I do not wish, however, absolutely to deny those facts, in the face of the affirmative testimony given by scientific men ; what I can say is, that I never have observed them."[3]

That is, indeed, the language of a man of science ; and if Mr. Beaunis had not found anything of this kind, he would have the right to make all reservations with regard to other observers. But chance willed that it should be otherwise ; here is what he himself published a little later :

"Mr. Janet's communication gives me an opportunity to mention a fact of mental suggestion that I observed a few days ago with Dr. Liébeault. The subject is a young man, a very good somnambule, in good health, a little timid. He accompanied his cousin to Dr. Liébeault's. The cousin is also a very good somnambule ; she is under treatment by hypnotism for a nervous affection. Dr. Liébeault endormed the subject, and said to him during the sleep : 'On awaking, you will do the act that the persons present will mentally order you to do.' I then wrote in pencil on a piece of paper these words : 'To kiss his cousin.' I showed the paper to Dr. Liébeault and to the few persons present, asking them to read it with the eyes only, without pronouncing even with the lips a single one of the words written on it, and added : 'When he awakes, you are to think intently upon the act he is to perform, but you are not to speak a word or to make any sign that might put him on the track.' The subject was then awakened, and we awaited the outcome of the experiment. Shortly after he

[3] H. Beaunis, "Recherches Expérimentales sur les Conditions de l'Activité Cérébrale," etc., ii., p. 90. Paris, 1886.

awoke, we saw him laughing and hiding his face in his hands, and this play went on for some time without other result. I then asked him: 'What is the matter?' 'Nothing!' 'What are you thinking about?' (No reply.) 'You know,' I said, 'that you have to do something we are thinking on. If you are unwilling to do it, at least tell us what we are thinking about.' 'No!' 'Then,' said I, 'if you won't tell us aloud, whisper it in my ear,' and I went up close to him. 'To kiss my cousin,' he said. The first step once taken, the rest of the mental suggestion was executed with a good grace.

"Have we here simple coincidence? That were surprising, indeed. Was it possible for the subject, during his sleep, to learn the meaning of the words I wrote on the paper, or could he have seen them? That is hardly supposable. Again, I am sure that none of the persons present could in anywise have put him in the way of finding out the act he was required to perform. Here plainly is something that upsets the received theories of brain-function, and, as for myself, till lately I was an unbeliever in facts of this kind. To-day I am convinced that they must not be rejected, successes being, though rare, far too numerous to be the result of mere chance; and from the moment that the question of mental suggestion was brought before the Society, I have believed that, strange as these phenomena might appear, I could contribute my quota."[1]

The transmission of a simple act of the will, *i. e.*, of a purely mechanical one, is easily performed if the subject manifests the phenomenon of attraction in a high degree.

"At Nottingham (says Lafontaine) I obtained the phenomenon of attraction in a young woman during somnolence, and from the first. Dr. Lightfoot, who was very incredulous, brought to a public seance a young woman to have her magnetized. In the course of a few minutes the girl was put in the state of somnolence; there was insensibility. Suddenly I perceived that there was attraction in my hand; I made her rise and walk toward Dr. Altenburow [*sic*]. While she walked I was ten paces behind her. I tried to attract her, and speedily she halted; her body swayed; then, though the doctor called her forward, she turned back toward me. I quit attracting her, and immediately she walked forward. When I again attracted her the same result followed—she halted, wavered, and turned back."[2]

Had Dr. Altenburow been a magnetizer he would have been able to thwart this influence by attracting the subject on his side. I made that experiment in Paris at the Pitié in 1882. Dr. Dumontpailler having endormed his subject, Miss Marie, since so famous, attracted her on one side, and her body would incline toward him at the risk of her falling out of her chair; then, after having made a few passes without contact (in order to enter into rapport, *i. e.*, to have the right to act) I attracted her on the other side, and thus we were able to balance her as though with cords, each of us attracting in turn.

[2] Lafontaine, "L'Art de Magnétiser," 3d ed., p. 90, Paris, 1886.

The phenomenon of attraction presents many shades of difference; these we will throw a little light upon when we treat of action at a distance.

Let us now consider purely mental will-transmissions, that is, experiments made without contact, without gestures and without attraction, sometimes even without a look (*le regard*).

A tentative demonstration of this delicate phenomenon was made in 1837 by Dr. Berna before an academic commission, but it failed utterly; at least so says the report of Mr. Dubois of Amiens, a masterpiece of ill-will. The members of the Commission were unable even to find any proof of the existence of somnambulism! Here is an extract from the report, referring to will-action:

"*Third Conclusion.*—The magnetizer had to prove to the Commission that, simply by the intervention of his will, he had the power of restoring, either locally or generally, the somnambule's sensibility. But as it was impossible for him to prove to us experimentally that he had taken away, done away, the girl's sensibility, it was for that very reason impossible for him to prove the restoration of the same; and, besides, it results from the facts by us observed that all the attempts made to that end failed completely."

This experiment is a very difficult one. In fact it involves not only a mental suggestion but, at the same time, a trophic ideoplasty,[1] and it is matter for surprise that Dr. Berna should risk such an experiment before men that knew nothing about magnetism, and who could not distinguish somnambulism from the waking state. The report goes on to say:

"One of the paragraphs of the program had this heading: 'Obedience to the mental order that the subject cease, in the middle of a conversation, from answering, verbally or by signs, a given person.' The magnetizer sought to prove to the Commission that the silent power of his will could produce that effect. But the facts of the seance show that, far from producing these results, his somnambule did not hear, even when he had, as yet, no intention of preventing her from hearing, and that she *appeared* (!) to hear again when he positively willed her not to hear. So that, according to the assertions of this somnambule, the faculty of hearing or not hearing was completely in revolt against the magnetizer's will. But, weighing the facts carefully, the Commission no more conclude that there was revolt than that there was submission; they found complete independence, and that is all."[2]

As for the phenomenon announced by Dr. Berna, and first described by Puységur, that we will examine in the sequel. For the present we would only remark that, despite its apparent simplicity, this experiment

[1] See Appendices II., III.

[2] For details see "Expériences et Considérations à l'Appui relatives au Magnétisme Animal, Thèse présentée et soutenue à la Faculté de Paris," 1834; also "Examen et Réfutation du Rapport fait par M. Dubois." Paris, 1838.

is exceedingly difficult. As I have already observed elsewhere, when the subject converses with anyone, *i. e.*, when he is in the state of active polyideism, it is very hard to act upon him mentally, first, because his "rapport" with the magnetizer is weakened by being shared with another person; secondly, and mainly, because in order that so slight an action may be felt, no other action must oppose it. Oftentimes persons engaged in conversation with one another do not hear those outside of their circle. The same phenomenon, comparatively, occurs in mental speech: several thoughts simultaneously occupy the mind of the subject; hence it is difficult for a new thought to find admission.

On the whole, I admire the robust faith of the physicians who, without knowing the conditions of so fleeting a phenomenon, were willing to run the risk of a set-back before a committee of unbelievers.

Magnetizers nowadays are more prudent. The reader will recall what Donato said to me when I asked him if he believed in mental suggestion. It seems, however, that he succeeded several times in presence of Messrs. Aksakof and Flammarion. First let us hear what he tells us himself:

"One day, at Paris, Mr. Aksakof requested of me a private seance. I consented, as I always do. Mr. Aksakof did not apprise me in advance of what he wanted to obtain, and I expected that I should have to reproduce my ordinary experiments.

"He required of me something totally different from what I had been accustomed to do. If I recall this circumstance, that is because it possesses an importance that will be patent to everyone. In fact, Mr. Aksakof wanted thought-transmissions—experiments that I never had made, whether publicly or in private. A little while after, Mr. Flammarion unexpectedly made the same request. I tried the experiment to gratify a thoroughly scientific curiosity, and all the thought-transmissions that were asked for were as successful as I could have desired. Had this experiment been habitual, one might have suspected the existence of an understanding, of a secret telegraphy between my subject and myself. But to say nothing of the minute precautions taken to prevent all subterfuge, I was asked for some new experiments to be performed on the instant. At first I refused to make the attempt; then, upon iterated insistance, I agreed *to try*, and though they were successful, they were so *almost in spite of me*. I brought no egoism into the thing; it is without vanity, and even without pleasure, that I declare my complete success, for I *know* that it will be impossible to content everybody always, and in particular always to satisfy myself in this class of phenomena, as fugitive as they are eminently curious."

Mr. Aksakof, in his report of the experiments, which he drew up with great care, says:

"It is known that one of the most widely heralded aphorisms of modern physiology is, that *psychic activity does not extend beyond the periphery of the nerves*. If, then, we could prove that man's thought is

not circumscribed by the limits of the body, but that it can overstep them, and act upon another human body at a distance, be transmitted to its brain, without any visible or any known process, and be reproduced by speech, movement, or other means, that were a fact of vast importance, *before which materialistic physiology would have to bend*, and which psychology and philosophy would have to take possession of, in order to give fresh support and a new development to their metaphysical speculations."

Mr. Aksakof is mistaken. There is no relation between mental suggestion and the question of materialism or spiritualism. Mental suggestion is a fact of action, not of the recondite nature of things, whereof we know nothing. Action at a distance is not a character peculiar to immaterial things—if immaterial things there be, and of such I know nothing. Electricity did not become a "spiritual" thing when the telegraph was invented.

"November 17, 1878, I went to see Mr. Donato at 2 o'clock, and after a few minutes' conversation we set to work.

"*First Experiment.*—I asked Mr. Donato to endorm Miss Lucile. He placed an armchair between the two windows of the room, a few paces from the wall; Miss Lucile seated herself in it, and within a few moments was endormed. We station ourselves at the lower end of the room, facing Miss Lucile. Then I take from my pocket a memorandum book and from it take a card, which I hand to Mr. Donato, requesting him to make Miss Lucile, solely by fixing his eyes upon her, to execute the movement indicated on the card. The writing on the card was: '*Etendre le bras gauche*' (extend the left arm). Mr. Donato takes the card, rises, stands alongside of me without a motion, and gazes on Miss Lucile. Instantly her left arm begins to stir, slowly quits the body, is held out horizontally, and so remains till Mr. Donato puts it back in the normal position.

"*Second Experiment.*—I hand to Mr. Donato a white handkerchief that I had brought with me, and ask him to cover with it the eyes and the head of Miss Lucile. The borders of the handkerchief reach her shoulders. We take our places again. I hand to Mr. Donato in perfect silence a second card on which is written: '*Lever le bras droit verticalement*' (raise the right arm vertically). Mr. Donato fixes his gaze on the motionless body of Miss Lucile, and soon her right arm, docile to the thought that directs it, executes the desired movement, always slowly, gently, stopping immediately when Mr. Donato turns his head to put a question to me with a look.

"I congratulated Mr. Donato on the success and asked him to remove the handkerchief from Miss Lucile's head and awaken her, so as to prevent all fatigue. [It would have been better to let her sleep quietly.]

"*Third Experiment.*—After ten minutes' conversation, Miss Lucile is endormed, and her head again covered with the handkerchief. We take our places and I hand to Mr. Donato a third card on which I had written: '*Mettre les deux mains sur la tête*' (put both hands on the head), and ask him this time to operate, not from in front of the subject, but from behind her. Mr. Donato expressed some doubts whether he would succeed under these conditions; nevertheless, he stood behind Miss Lucile and made the attempt, but in vain. That did not

surprise me, the general rapports of polarity between the operator and his subject having been reversed."

We must not call in an unknown cause. Has the spiritual soul, then, a right side and a left? Besides, in acting from a great distance one cannot know what is the position of the subject. With regard to this check Donato writes:

"Without discussing the question of polarity, I would remark that my objection was not based on that phenomenon. The objection simply was that, stationed behind Miss Lucile, I could not through her body give action (*actionner*) to her arms, *placed out of sight for me.* It is as though a sharpshooter were required to hit a mark behind a wall, and at which, therefore, he could not take aim."

From this remark it follows that Mr. Donato believes rather in direct action upon the member aimed at than in action through the brain as an intermediary. I cannot say that the theory is erroneous, for I myself have witnessed the excitative action of the eye (*regard*). But even should light-rays reflected from the eye of the operator, or should any other cause unknown, by irritating the organ directly, facilitate the local action, still they are not absolutely necessary, and the reader will remember that most of my experiments with Mr. M——a[1] were made without the physical action of the eye, and without gestures. But to return to Mr. Aksakof:

"At this moment I came up to Mr. Donato, and a remarkable phenomenon occurred. Wishing to ask Mr. Donato to concentrate his thought upon the occiput of Miss Lucile, my hand, while I was standing behind her, was inadvertently brought toward her back to point out the place I spoke of. As soon as my hand had come near her back (it was still some inches away from it) the body of the subject bent forward with a sudden movement. Thus did I obtain, in a way as unexpected as it was conclusive, confirmation of the phenomenon of polarity, or of attraction and repulsion, which I had already observed in the public exhibition."

This phenomenon proves nothing in favor of polarity. Any person not in rapport who should touch her with either left hand or right, or who should bring his hand near to her, would have obtained the same repulsional effect. The subject recoils because nearness of one not in rapport causes her discomfort. The phenomenon proves only that what is called magnetic rapport does not consist solely in concentration of attention, but rests also on a physical basis.

We might say that the act of the magnetizer sets up in the molecular motions of the subject's nerves a special tonality in accord with that of the magnetizer, and that then a person who does not possess

[1] Doubtless "Mr. M——a" (*M. M——a*) is an error of the printer or a *lapsus* of the author's pen. We know *Mrs.* M——a, but who is *Mr.* A.? A little further on a probable misprint of "Mr. L" is changed to "Miss L."—*Translator.*

this—that is to say, who presents a different tonality—makes upon the subject a disagreeable impression. In that case it suffices to make a few passes fornent the point in question, in order to have the right to touch it.

I have observed one case, and only one, among hundreds, where the magnetizer himself durst not touch the subject without giving the latter a disagreeable shock. I was much surprised, and sought to verify the fact. The cause of the phenomenon was, that the magnetizer always endormed his subject from a distance of several paces, never beginning with contact or with passes made anear.

That would not have sufficed with other subjects, but it sufficed with Miss L., who was remarkably impressionable. I myself endormed her by touching her hands and by making passes anear, and the general hyperæsthesia was not manifested. I communicated to her a dynamic state like that of my own body. (The terms I employ here I am unable to define more accurately, but the thing seems to me to be not improbable.) Anyhow, the attention [of the subject] does not alone suffice to explain this phenomenon, for it may take place without the possibility of the subject's guessing who touched him,[1] and there are other phenomena of this kind that attention cannot explain.

"'If you will let me act with my hands,' said Mr. Donato to me, 'I am confident I shall succeed.' 'Act, then,' I replied. And, indeed, as soon as he (still behind the subject) brought his hands near Miss Lucile's shoulders, making a few passes toward the elbows, the arms began to move upward and both hands were laid upon the head."

But, then, there was no longer mental suggestion, only the effect of *magnetic attraction.*

"*Fourth Experiment.*—Miss Lucile still endormed, with the handkerchief over her head. I give to Mr. D. (Donato) a fourth card, on which I had written this: '*Réunir les deux mains comme en priant*' (join the two hands as in prayer), and I take a place on a sofa to the left of Miss L.; the better to observe all Mr. D.'s movements. He stood motionless five or six paces away from Miss L., facing her, and with his eyes fixed upon her. Her hands, which had been restored to their natural posture by Mr. D., were raised slowly, were brought together, even the fingers were crossed—in a word, took the pose of prayer. The experiment performed, Mr. D. removed the handkerchief and awakened the subject.

"*Fifth Experiment.*—After resting ten minutes, Miss L. again takes her seat in the armchair, and Mr. D. endorms her anew. I pass to Mr. D. a fifth card: '*Faire un nœud avec un mouchoir*' (make a knot on a handkerchief). 'See how we are going to work this time,' said Mr. Donato, and stationing himself a little behind Miss L., he stretched his hand out above her head, but without touching her. She rose from her chair. Mr. D. directed her toward the table on which, unbeknown to her, the handkerchief had been laid by me. Miss L., obeying the attraction of the hand, approaches the table, Mr. D.

[1] See the experiments mentioned on p. 23.

approaching also, while keeping still at the same relative distance behind Miss L. I was alongside Mr. D., and we both followed, with increasing interest, the movements of the subject. Little by little her hands steadily approach the handkerchief, take it by one corner, fold it, turn the ends over each other, and, lo! the knot is made. Mr. D. himself was amazed. This time there was no simple effect of will, but a thought transmitted and executed.

"*Sixth and last Experiment.*—It was almost useless to continue; but as Mr. Donato insisted, I once more passed to him a card. On it was written: '*Toucher l'oreille gauche avec la main droite*' (touch the left ear with the right hand). Without moving a muscle and without a sound, Mr. D. fixes his gaze on Miss L., a few paces distant. I was alongside of Miss L. and nearly facing Mr. D., so as to observe his slightest movements. Soon the subject's right arm leaves her side and executes the order in three successive movements; first it is brought toward her breast, then moves toward the ear, and up to it, finally one finger is extended and touches the ear."

No details are given as to the state in which Miss Lucile was during these experiments. But from the record it would appear that she neither spoke nor acted of herself; hence she was not in active polyideia.

On the other hand her state was not one of profound paralytic aideia, for she did not fall inert. It was therefore an intermediate state.

I take occasion from Mr. Aksakof's excellent account to raise the following question:

Must one distinguish between *will* transmission and *thought* transmission?

In the quotations just given it has been impossible for me to do so. I was compelled to treat the two phenomena as one. But are they in fact distinct? Can we transmit and cause the execution of an act of the will without at the same time transmitting a thought or a number of thoughts?

The question is a very complex one. Take for example Mr. Donato's experiment last cited. Miss Lucile was to touch her left ear with her right hand. Had this movement been executed by attraction through gestures, as in the first portion of the fifth experiment, there would have been no communication of thought, but no more would there have been transmission of will. The act would have been purely physical, even though we should grant that somnambulic attraction is not a direct but a reflex fact. But as this experiment was made at a distance and without gestures, Miss Lucile must needs have divined what was required of her, the more because though the movement was executed slowly, it was, nevertheless, executed well, and without hesitation, not after the manner of one who gropes in the dark. Only one influence from without was possible, that of the eye of the operator. We know that a fixed regard directed upon a portion of the

hyperæsthesic body calls forth in certain subjects and in certain states a local action that now is inhibitive (insensibility and contracture), anon dynamogenic (excitative). Consequently, Mr. Donato could, by fixing his gaze upon his subject's right arm, produce therein an excitation, an agitation, in short an impression of whatever sort, which, being felt by Miss Lucile, would lead her to guess that she had to perform a movement with the arm. But there the action of the eye ends. Mr. Donato could not by a look cause the arm to extend itself, nor could he with the eye indicate the movement ordered. Consequently we must concede the fact of transmission. But transmission of what? Of will or of a thought? A thought was not of itself enough. Were the thought alone transmitted, the subject would have the mental image of an ear touched by a finger, just as she might have the image of a bird flying, of the ace of spades, etc. She must needs at the same time feel desire, *impulsion* to realize that image. On the other hand, is the impulsion by itself sufficient? Yes! There is no doubt that subjects can feel by transmission, by sympathism, by *mental imitation*, an impulse to perform a movement, without knowing either why they do it, or what it means, or what it will result in. In such a case there is simple will-transmission. It is only the mental impulse, the tendency, the volition, that is transmitted. And I even believe that this is what occurs oftenest. Were the subject to be asked, say at the beginning of the fifth experiment, she could not tell what she wanted to do; but, little by little, driven by impulses coming one after another, she finally performs the action willed, perhaps without even knowing what she does (for the monoideic state is unfavorable to a generalization of acts or of ideas). Suppose, for example, the order is to take some object and give it to somebody; the subject will do what is required, and then, if you ask him what he has done, he will say that he *had to take up something* and carry it to *somebody*, knowing neither to whom, nor wherefore. If, in such a case there is transmission of thought, it belongs among the unconscious phenomena of secondary rank, and only the will is perceived under the form of unconscious tendencies of prime rank.

In short, though the two transmissions may be manifested separately, usually they are combined.

And is transmission of sensations a necessary concomitant in these two phenomena?

Not a necessary one, but useful.

I have many a time, for example, observed (though in most instances this phenomenon lags a little) that a strong action of will directly produces in the subject sensations analogous to itself. An act of will that is strongly affirmative or strongly negative is always accompanied by certain agreeable sensations in the first case, disagreeable in the second, to which are added also sensations resulting

from inchoate gestures of affirmation or negation. The former are by their nature attractional, the latter repulsional. Now, the subject often feels these sensations. You mentally exclaim to him: "No, not that!" and he halts or he retreats.

We will bring this chapter to a close with two interesting observations by Dr. Perronet. There will be found direct will-transmission combined with facts of mental suggestion of ideas. I invite the attention of the reader particularly to the details of an apparent *phrenhypnotic* action; they will help us to appreciate in the next chapter Braid's illusions.

First Observation.—"On the night of May 2–3, 1883, I was called to attend a person of eighteen years. Nervous, impressionable, frivolous, she had been angered during the day. I found her stark—absolutely rigid and insensible. I applied my fingers over the eyeballs; first there was a slight tremulation, and then the lids were opened. The members now became limp, did not retain the postures given them; if raised and let go they fell inert.

"After a brief period of waking, during which the subject spoke a few words consciously, the rigidity returned; application of the fingers over the eyeballs did not overcome it till after a morphine injection; the members retained the postures given to them.

"Then were performed, at my order, the most varied movements: applying the fingers to the right side of the cranium I obtained the movements ordered for the members of the left side, and *vice versa.*

"This I attributed to the decussation, in the pyramids, of the nerve-tubes coming from the cerebral hemispheres, in virtue of which a nerve-tube belonging to the left hemisphere of the brain passes to the right in the medullary fasciculus, and consequently controls movements and sensations in the right side of the body. Of course, the inverse is true of the nerve-tubes that have their rise in the right hemisphere of the brain.

"I made the subject talk by touching the left half of the cranium; in so doing I was governed by the idea that the third left frontal convolution is the seat of articulate speech. When, being under the influence of this idea, I touched the right half of the cranium, I obtained no response, for the reason that, in my innermost thoughts, subjectively, theoretically, I expected none. But once I mistook one side for the other, and the subject made answer to me though my finger was placed on the right side of the cranium, to wit, the side opposite to that of the convolution that Broca assigns as the seat of articulate speech.

"Speech ceased as soon as I recognized my error. I inferred directly that my thought alone was active in the producing of these phenomena, and that to apply my fingers at such or such a point of the cranium to obtain this or that result, was an act of supererogation.

"Having, then, obtained the shutting or opening of the eyelids, pouting, smiling, etc., by placing my fingers on the muscles that govern those actions, it occurred to me to avoid all contact with the subject, and, stationing myself several yards away, to ask of her a repetition of the acts and speeches before obtained by the aid of digital contact. The subject obeyed all my orders orally expressed.

"I then bethought me of communicating my orders to her mentally; I was much surprised to find them executed punctually. And I was more surprised when, on requesting the persons present to take my hand and think in turn of some act, that act was performed by the subject automatically.

"A whiff of illuminism and of spiritism at that moment, I confess, entered my brain, so I thought it best to let my ideas upon this question lie over for a year before I should give them to the public.

"At last, after having prolonged the experiment for four hours, I awakened the subject by blowing into her eyes; the awaking was instantaneous, and left no consciousness of the phenomena that arose or were produced during the crisis.

"*Second Observation.*—July 4, 1883, Miss X., hysterical, chloranæmic, aged 21 years, who had witnessed the facts contained in the foregoing observation, and whom I was treating for lymphangitis of the arm, had just taken a pretty strong dose of syrup of codein.

"At this juncture I arrived and this is what I observed: Eyes surrounded by dark rings, drooping upper eyelids, contraction of the pupils, laughing and crying without cause, clonic agitation of the members; then after three or four minutes a strange stare, complete rigidity and insensibility. The rigidity disappeared after application of the fingers over the eyeballs (phenomenon of hypnotization), and was succeeded by a limpness of the muscles which allowed postures imposed on the members to be retained.

"When I press upon one eye only, the rigidity is retained in the corresponding half of the body, and the members of the other half take and keep all the poses determined by my impulsion; the subject replies to all my questions if the rigidity disappears in the right side of the body, consequently, if I have compressed the left eye; when pressure is on the right eye alone I obtain no reply.

"Laughter, tears, walking, singing, calculating, statuesque poses, and other phenomena were produced at my order with mathematical precision.

"The subject cannot play the piano; I made her play on that instrument airs from "L'Ombre," "Le Chalet," "La Traviata," etc. To obtain this result I placed my left hand on the left side of the cranium, played the airs with my right, and ordered the subject to repeat them; the whole was reproduced note for note. I had the same success when I asked for an air already played in a different key; to this end it sufficed for me to give the first note in the new key.

"My hand being applied to the right side of the cranium with the preconceived idea that the seat of articulate speech is situate in the left cerebral hemisphere, the subject was deaf to all excitation, whether verbal or musical. In the midst of a series of quadruple quavers, I suddenly broke the contact of my hand with the left half of the cranium; then the fingers of the cataleptic pianist stood suspended over the next note, which was sounded when I gave the order to do so by putting my hand on that side of the cranium again; the remainder of the piece was played without any modification.

"Finally, making an effort of will to free myself from the idea that such or such contact is necessary to obtain such or such act, I asked her in an imperative tone, from a distance, to go on with an air she had begun to play. At the end of the piece she stopped and was like a statue, fixed in the pose necessary for sounding the last note. 'You

are going to play *Quand je monte Cocotte*,' I said, 'till I tell you to stop; put a little expression into it, a little soul.'

"Then came some horrible music; she repeated a couplet over and over. All that the company present could do to drag her away from the piano and to put a stop to the air I had suggested to her was futile. Like the broom-handle Lucian of Samosata tells of, which being set to work by a magic word, could never cease working till another more or less cabalistic phrase was spoken, the subject played, played, played.

"At last, judging that the experiment had been carried far enough, I gazed sternly at her, with strong, decisive will to put a stop to the music: I gave forth no sound, made no movement; I was several paces back of the cataleptic subject. As soon as my will was clear in my consciousness, without any need of word or sign, the subject came to a full stop in the very middle of a musical phrase. The like of this may be seen in the phenomenon of supersaturation; the slightest disturbance in the supersaturated solution produces sudden crystallization.

"'What is the name of the state in which you are?' 'Ca—ca—ca—ta—lepsy.' (N. B.—When awake she does not know what 'catalepsy' means.) 'Is it anything serious?' 'No!' 'Can any one put you in that state?' 'No; only the doctor.' 'What is this power that he has over you?' 'Something that I do not understand.' 'Explain!' 'I don't know what; it is the force of the blood.'

"I tell her to say how many persons are present, and to give their names. Having myself reckoned the number amiss, she gave the number I had in my mind; as soon as I had rectified my error she gave the correct number.

"A lady having come to ask money of her, I requested the cataleptic to give her some. She went straight to the piece of furniture in which she had been accustomed to keep her purse; not finding it she was worried; when some one whispered in my ear that it was on the piano, the subject knew it as quickly as I did, and suddenly changing her expression of ill-humor to an air of satisfaction, she ran to the piano, took the purse, and took out ten francs to give to her creditor. I begged the latter to call the next day, for I did not wish to make use of a scientific experiment to force the subject to pay automatically; I gave the lady to understand that it was hardly right for her to pay herself. She gave the money back, but my experiment was made. I awakened the subject by blowing on her eyes.

"From the foregoing facts I inferred that the cataleptic traced[1] her answers on my thoughts rather than on the reality; that she was more impressed by the psychic phenomena of my brain than by those of the outer world; in short, that whether she perceived aright or amiss, she was quite insensible to all excitations save such as came from me; that she was as it were an extension of my own consciousness.

"I observed this subject many times. In the state of catalepsy she was ever deaf to all impulsions not given to her by me directly or by me delegated to others; her personality was lost in mine, as the personality of the Fakir is lost in Nirvana.

"Of all the subjects observed by me none presented this disposition in anything like the same degree."[2]

[1] *Calquait*—As when one copies outlines on tracing-paper.—*Translator.*

[2] Claude Perronet, "Du Magnétisme Animal." Louis-le-Saunier, 1884.

Mr. Perronet's experiments, which were so successful, were made on *cataleptics*. Those of Dr. Puel, too, were on cataleptics. Those of Drs. Comet and Despine were likewise made on cataleptics. Finally, we may remark that it was in catalepsy that Dr. Petetin came unawares upon the phenomenon of mental suggestion. It would seem therefore that there is some sort of relation between catalepsy and suggestion. What is it?

As we have seen, the psychic state most favorable to mental suggestion is *monoideism*. Now *catalepsy*, as an outward phenomenon, *is simply a muscular* manifestation of a *monoideic tendency in the brain.* The subject keeps the one selfsame position, for he is capable of but one selfsame thought at a time. The idea of a given attitude dominates his brain without limitation. "There it is, there it remains."

CHAPTER VI.

WILL-ACTION AND THE QUESTION OF "RAPPORT."

WE find very few experiments of the kind here referred to in the history of magnetism; not only because they seldom were successful, but because, thanks to Deleuze's influence, *all experiments* whatever were banned—that is to say, all that were foreign to the question of treatment. Aubin Gauthier,[1] who wrote a sort of encyclopædia of magnetism, says upon this matter:

"There are somnambules that hear their magnetizer without any need on his part to address them in words; indeed, there are many such. As a rule, a somnambule that has had rapport only with one magnetizer, understands him without his speaking. One may test this, not for the sake of the experiment, but because there are cases in which this faculty is very useful. If it is feared that the somnambule will tell, in presence of a third person, things that the latter ought not to know, he is mentally made to understand that he must keep silence, just as in ordinary life one speaks with the eyes or with a gesture. So, too, if it is feared lest in the course of a consultation given to a patient whose case affords no hope of a recovery, the somnambule may be indiscreet; again, the will is employed, and the somnambule understands, unbeknown to the patient. Otherwise, this means is not to be used without necessity."

This humanitarian purpose was predominant, as has already been observed, in the first two periods of magnetism—that of Mesmer's "*baquet*"[2] and that of somnambulism. Puységur also forbade use-

[1] A. Gauthier, "Traité Pratique du Magnétisme et du Somnambulisme," p. 594. Paris, 1845.

[2] See HUMBOLDT LIBRARY, No. 113, "Hypnotism," p. 6.

less experiments; but enchanted as he was by the mental sensibility of his first somnambules, Victor, Magdeleine, and a few others, he authorized the experiment mentioned by Gauthier, and in his enthusiasm even maintained that we can always make the somnambule cease talking and that we can make or break, mentally, the rapport of a somnambule with a third person. I will quote in full the passage relating to this.

Puységur recognizes three principal characters as distinctive of *complete* somnambulism:

1. "Isolation" (rapport with the magnetizer exclusively, insensibility to all the subject's surroundings);

2. "Concentration" (meaning that all the activity of the subject is concentrated inwardly). Puységur knew nothing of *spontaneously active* magnetic somnambulism;[1]

3. "*Magnetic* mobility" (mental suggestibility and attraction at a distance).

"The third character of complete somnambulism (he writes) is magnetic mobility; that is to say, a patient in this state is *always* more or less sensible to *the very thought* of the magnetizer. I say 'more or less,' because there are patients whose muscles sometimes grow numb in somnambulism, so that they cannot stir save with much difficulty; and there are others whose drowsy concentration is so profound that it is no easy thing to rouse them. Hence, you will not make them all alike get up, walk, follow you, sit down, take a cup off a table, or accept what you may offer them mentally and by the simple act of your will. But what you will *always* succeed in, without any need of touching them or speaking to them, is the putting them in rapport with persons that you wish them to hear. The success of experiments of this kind, *depends, however, solely on the magnetizers, not at all on the magnetized*, who, like compass-needles on their pivot, are quite indifferent as to what directions you may wish to give them, provided the influence is good."[2]

How could so good an observer speak with so much confidence of so delicate a phenomenon?

For many reasons:

1. It appears, whatever the hypnotizers may say, that he was not mistaken in saying there are differences between individuals. Not only is it conceivable that some persons may not be able to concentrate their thought (this phenomenon may be easily observed by making an experiment in *Cumberlandism*); but further, it seems to result from the differences in the character of the somnambulism obtained by different

[1] Magnetic sleep with rapport and spontaneously active is rather rare. It manifests itself only when the subject is magnetized in spite of himself, or when there is a somnambulic awaking out of a state of profound aideia, the awaking being occasioned by a thought dominant in the waking state.

[2] A. M. J. Chasnet de Puységur, "Recherches, Expériences, et Observations Physiologiques," etc., p. 45. Paris, 1811.

observers, that the psycho-physiological individuality of the operator counts here for something. I know, for instance, a person who, without willing it, obtains nearly always paralysis-phenomena; others who bring about hyperæsthesia mostly; others who cannot obtain more than a slight drowsiness; others who always determine a disagreeable state—a fact that for a long time surprised me; for in all my observations, except the cases of two or three epileptics and one or two hysteriacs, I have always obtained a state highly agreeable to the subjects; indeed, this it is that has brought to me so many amateurs, so that I never have needed to seek for subjects. In a word, there are personal differences, and if I have not succeeded in repeating Puységur's experiment, or anything like it, that may be due to an individual difference or to some irregularity inherent in my way of experiment in that particular case.

I do not wish to exaggerate the importance of these observations. The individuality of *the subject* is, after all, the principal cause, the most obvious cause, of these phenomena.

A person that is distinctly sensitive to the hypnoscope can be hypnotized by anyone.[1] Differences begin to appear only in the vital action, and are seldom sharply defined.

2. As we have seen, Puységur knew nothing about active somnambulism, that is to say, a polyideic state that usually withstands mental action. Hence he saw no obstacles except such as are presented by too profound a state, with drowsiness, torpor, rigidity; that is, the state of paralytic or tetanic *aideia*, which, when it has a strong hold, also withstands mental action. Consequently, he acted only on states more or less akin to monoideism.

3. Finally, we must not forget that he speaks only of complete somnambulism with rapport, and that it was his luck from the beginning to find excellent subjects: that may have increased his confidence.

However that may be, this fact has been noticed by an excellent observer, whose book recommends itself to the inventors of hypnotic novelties.

"About the same time (says Dr. Despine, Sr.) there arrived at Aix the Count Paul D., a superior officer of the Russian Imperial Guard, who, having heard of my patients, showed a desire to see them. He had previously given some attention to magnetism in company with Dr. Pizzati, who wrote to me from Florence, introducing him. Though he no longer made magnetism the subject of his studies, he remembered his former great magnetic power and spoke of it with some satisfaction. He was curious to know to what extent he still possessed it. I cheerfully complied with Mr. D's. wishes, and, with the consent of my two patients and of their family, I put them in

[1] Yet I have been assured that a hospital doctor in Paris never could obtain sleep, even in patients that were exceedingly easy to endorm.

rapport. From the first I was amazed at the enormous magnetic power he exercised over them. His gaze alone 'petrified' Estelle, and a few quieting passes round about the præcordial and epigastric region, at the distance of five or six inches, were enough to relieve Miss Isaure of her terrible suffering, the seat of which was the pneumogastric nervous system, and which for many months never ceased, save during the state of catalepsy or of ecstasy, or perhaps during her natural sleep, which was rare and nearly always troubled by dreams and visions. What astonished me most in the Count D.'s magnetic power over the latter patient was, that he was able *by sole act of his will to suspend in her the magnetic rapports* already existing between her and me, when he wished to act upon her by the will alone, and to *re-establish* them at his own will or the will of others. I had been Miss Isaure's physician from the time of her coming to Aix, and I seemed to have her entire confidence, but Mr. D. soon deprived me of that, and so the case stood till he went away. Whence this power of sympathy? I know not, but the fact nevertheless remains. I have seen it repeated many times, and Miss Isaure *heard me* or *heard me not* according to Mr. D.'s good pleasure. And quite certainly this could only have been produced by act of the said Mr. D.'s will, for he did not touch her either directly or indirectly. I have seen the phenomenon again and again. He and I even communicated in writing, to remove from the minds of those present all suspicion that perhaps the patient, albeit her eyes were completely shut during the whole time of her crises, could hear us, could know by signs, and so conform out of complaisance to the will of her magnetizer. The Count D., furthermore, varied the phenomena absolutely according to my good pleasure. He spoke not a word, yet when I handed to him my orders in writing, he was able to have them executed by the patient *at the moment willed and fixed by me then and there;* and if I changed the orders, after first giving them in another shape, Miss Isaure executed them, not as first given, but as given just a moment before. Mr. D. had told me of this feat, saying he had performed it often already. I was very curious to see how he would carry out such a program, for I did not believe it possible then, and even still I have a difficulty in believing that the thing can be done, in spite of all that the magnetizers have said about it, of all that has been written about will-force, and all that I myself have witnessed time and time again.

"From all this the reader will naturally infer that I brought to the experiment all possible attention, to see clearly what should take place so as to discover the law that governed it, and to make such inductions as would help me to appreciate justly the cause of the modifications to which it unquestionably must be exposed in the various somnambules. I was therefore all eyes and all ears, and no one could give closer attention than I to the gestures, the looks, the slightest movements of both. And yet, beyond the possibility of doubt, and, I confess, much to my surprise, I saw Mr. D. do away the rapports subsisting between the patient and me; I saw these rapports, these sympathies, renewed, again suspended, and so on, and that by a single act of his will—or perhaps, if you will, by a fascination the nature and *modus operandi* of which were absolutely unknown to me then as they still are—and it constantly produced its effect when my thought or the thought of any other person in the company *passed* [to

the patient] *by the will of Mr. D.* This phenomenon *cannot* be explained as many other phenomena can, *by the mere reading of the magnetizer's thought*, done by a magnetized subject (a phenomenon that is much more common than people think, in the nervous state of *crisiacs*, whether magnetic or spontaneous). Indeed, to produce it, not only must Miss Isaure have been able to read the thought of the person acting upon her, but, furthermore, the magnetizer must have by his will paralyzed the organ which maintained the neuropathic rapport between her and me, and all this must have been simultaneous. Without the concurrence of these two conditions the solution of the problem would have been incomplete. However that may be and whether the explanation here given of the phenomenon is satisfactory or not [plainly, it is not a sufficient one], it is a positive fact that so soon as the will of Mr. D. had re-established the rapport between Miss Isaure and me, if I said to her, 'But why, madam, did you not answer me when I addressed you a while ago?' she replied at once, 'For a very simple reason, sir; you did not ask me any question.'"[1]

Thus Puységur observed correctly, and the phenomenon is possible. We may suppose that a concentration of the will on the part of Mr. D., directed toward Miss Isaure, in the first place diverted the existing rapport with Mr. Despine toward Mr. D., that is to say, toward *a more powerful dynamic center*, and then by successive efforts communicated to the subject such impulsions as Mr. D. willed. The staying of these efforts, the displacement of this center, freeing the nervous system of Miss Isaure from its leading-strings, re-established the rapport with her habitual magnetizer. It is as if two telegraphers were to snatch from each other the conducting wire upon which transmission depends.

Imagine a highly sensitive galvanometer connected separately with two coils, A and B, of heavy wire; both have a magnetic core, but the magnet of coil A is weak, while the magnet of coil B is strong. If these magnets are at rest there is no action, and the galvanometer will not stir. But the first, by a series of displacements, induces in its coil a series of alternating currents. The galvanometer needle oscillates, and it will be in a constant state of wavering so long as the movement of the weak magnet in coil A continues. But now the other begins to vibrate; its displacement changes the molecular tension of the spirals of coil B; currents are produced, and these, being stronger than those others, determine a more considerable re-action of the needle and predominate over the influence of coil A, causing the galvanometer needle to go through all the corresponding movements. The very sensitive galvanometer represents the subject, and the two coils correspond to the two magnetizers, in whom the intense interior action produces intense molecular vibrations, which radiate outward.

[1] Dr. Despine, père, "Observations de Médecine Pratique," p. 176 *et seq.* Annecy, 1838.

The wires—here the analogy is less patent—represent the rapport. Cut the wires, and the galvanometer is stock-still.

It is much the same in the magnetic action, as it is called, of a living organism. If rapport is not set up by preparatory magnetization, or at least by prior magnetizations, I believe mental action will have no result.

There are some facts that seem opposed to this view. Thought-transference has sometimes been obtained with a few persons that never were magnetized. But when we examine the facts closely, we find that in the first place the subject was always *advised beforehand*, that always his *expectant attention* placed him in a more or less abnormal state, and that always, *prior to obtaining any result whatever*, the operator was obliged to concentrate his thought *with the purpose of influencing the subject*—and that is pretty nearly equivalent to a magnetization.

Hence I believe that Despine observed the phenomenon well; *there is no mental suggestion without magnetic rapport.* He observed that Mr. D., if he would act on Miss Isaure, had first to break the rapport with Mr. Despine, and then establish his own. That observation no doubt seemed to the reader insignificant, yet it possesses an importance of its own.

"But," it will be said, "it all amounts to the same thing, for Mr. D. acted in the same way in order to set up rapport as he did to make the subject obey an order."

Yes and no! He acted in the same way, for he acted mentally, but the action is not altogether the same. To establish rapport you *call* the subject mentally, you *attract* him, that is, you draw his attention by an effort, which, causing the particles of—I know not what—to vibrate, is propagated and reaches a sufficiently sensitive galvanometer; while to carry out an order, you represent it to yourself inwardly and you *press* (*on pousse*) *the subject on*, mentally, in the direction you will, striving the while, above all, to think *clearly* of what you want to obtain. The difference is much like the difference between the "hallo-o" you shout into a telephone to attract the attention of whomever you wish to address, and the tones of ordinary conversation.

"Yet there is a mental action in both cases; and if there is no mental action without rapport, it must also be admitted that there is no rapport without mental action."

Yes; there is rapport without mental action. The very presence of an organism endowed with a high nerve-tension, a well-balanced vitality of the molecular movements, can act *physically* on a subject eager for such a vital energy, and may prepare the way for a purposed mental action. Catalytic actions of this sort are seen even in inorganic chemistry.

The vicious circle, then, is apparent only. It is due simply to the imperfectness of our speech.

Certain German psychologists who love useless questions, have worried much, thinking how it is that a sleeping man may be awakened by an impression, while he is insensible to impressions.

Of course if you define sleep "a non-impressionable state," you never will understand awakening by an impression.

Fortunately, all things are relative. The sleeper does not perceive, but his unconscious does perceive perfectly well, and there is no boundary between the conscious and the unconscious.

In a state of profound aideia mental suggestion fails; but if the state be less profound, it succeeds in doing one thing, to wit, in *nudging*[1] the subject and producing a comparative awaking, a transition to a state of more sensibility, and then, by persistence, the suggestion may succeed absolutely.

In short, we see the importance of rapport for the manifestation of the phenomenon we are considering; and though we desire to touch as little as possible upon questions that are beyond the scope of our work, we shall be obliged to elucidate it somewhat.

What is meant by this "magnetic rapport?"

The phenomenon so called is a very complex one. In it is involved the whole question of magnetism. For hypnotism it has no meaning. A hypnotized subject hears everybody. A magnetized subject hears only his magnetizer. Nay, more; *he hears his magnetizer only when his magnetizer addresses him.*

Standing beside a somnambule, and conversing with him, you may freely answer other persons, address them, speak to them about the somnambule, ridicule him. *He hears nothing.* But when you yourself shall address him he will reply to you, and will execute your orders.

Why? How comes it that another impression, in all respects identical, at the *physical* point of view, is not noted by the somnambule, when it is not accompanied by a certain intention?

Is the thing lacking in the latter case a *mental action?* Doubtless! But the case is not so simple as it seems. We cannot affirm mental action simply on the basis of this phenomenon. In most cases mental action is absent from the phenomenon, at least in the sense of will-transmission. Yes, the intention makes all the difference; but if we observe closely we see that we change our *attitude* perceptibly when addressing other persons. Usually we turn about; above all, we give a different intonation to the voice, and the brain of our subject is not regulated for that intonation.

From this we may see the importance of involuntary suggestions.

[1] French, *exciter*. But the words excite, excitement, etc., seem to denote a higher degree of commotion than is always implied by *exciter*. Nudge is an appropriate verb here—and a picturesque. *Stet!*—*Translator.*

A mass of valueless observations in hypnology might have been spared had it been known :

1. That hypnotism is not to be confounded with magnetism ;

2. That the magnetized subject divines our intentions up to the point of anæsthesis or to that of hyperæsthesia, according to the intonation of our voice.

All this, again, without mental suggestion. Now add the action of suggestion that manifests itself from time to time, at least indirectly, *by unconscious perceptions of the secondary order*, and you will see how great is the chance of error in a study made under such conditions.

Rapport results :

1. From a concentration of the subject's attention, directed solely toward the magnetizer. (This is the more usual case, and very often this explanation suffices.)

2. From a special *psychic adjustment* (*réglage*), partly obtained through this concentration, but principally brought about by the magnetizing processes, and kept up by involuntary indications conveyed by the attitude of the magnetizer, his voice, etc. (This case is less frequent.)

3. From *an individual physical action* (which we will describe in the sequel, but which is seldom evident).

4. From a *mental suggestion.*

There we have magnetism at flood! *An individual physical action :* that is magnetism, whether fluid or not. When the operator comes into play, not as a bright button,[1] but as a live body, as a dynamic center whose presence is not indifferent, that assuredly is magnetism.

Well, yes ! That must be admitted, else we must renounce the understanding of certain facts.

An eminent professor in the Collège de France, whose originality of views and exactitude of experimentation I esteem highly, has said concerning this subject :

"Science is indebted to Braid for having drawn the line sharp between the erroneous pretensions of those who believe more or less in what purports to be animal magnetism or *neuric force*, that may issue from the nerves of one individual and enter those of another, and the very interesting facts that may be produced in sundry parts of the nervous system of an individual, under the influence of a special irritation coming from another part of that system."

This disposition to substitute, as far as possible, the positive for the mysterious, I understand and approve ; but why be more Braidian than Braid? That excellent observer could not abide long in the erroneous belief that the phenomena he produced and those produced by magnetizers are identical. He rejects the concurrence of the

[1] *Bouton brillant*—a button, or knob, of polished metal, or the like, used in producing *hypnosis.*—*Translator.*

"fluid" in his experiments, and strives to substitute for an impalpable objective action a verified subjective one, and he is right: every one ought to refuse, as far as possible, to admit new forces; but Braid does not say, like the hypnotizers of our time, that magnetism does not exist, and that hypnotism takes its place completely. He says only this: "We were unable to discover the sympathetic influence that other experimenters, 'tis said, have found." These are the words of the true man of science. But there is something more: despite his dominant disposition, which was eminently scientific, to eliminate magnetism from hypnotic action, he came to recognize the error of supposing that the one took the place of the other completely. He says:

"The following remarks of Mr. M. Brookes, the well-known lecturer, on animal magnetism, will throw still more light on this controversy. *On learning that I had changed my opinion* upon the subject of identity, he said: 'I am very glad you have believed it your duty to change your original view as to the identity of your phenomena with those of mesmerism. From the first day I admitted the value and importance of your discovery, but I could not accept this identity, and I found fault with you for the violence with which you condemned the partisans of animal magnetism, because they could not agree with you. I believed, and still believe, that you were in the wrong in that controversy, and that in fact you were unfair to yourself, for you have in fact discovered a *new agent*, and not simply a modification of an agent already known.'"

Leave therefore to Braid the things that are Braid's, and to Mesmer the things that are Mesmer's.

Mesmer was in the wrong (he was often in the wrong, but in this case was particularly in the wrong), in that he came *first*, and one is seldom received kindly who comes too early. Braid rendered great service to science by verifying, according to exact methods, a certain number of facts already discovered by the magnetizers, already authenticated by an academic commission, already explained subjectively by Faria, Bertrand and Hénin de Cuvilliers, merely presented by him in a more positive and more scientific light. That is all he did, and that is enough. But it is not enough for those in our day who continue his labors.

"To-day," says Dr. Bottey,[1] "the mysterious is dead, and with it animal magnetism, which has ceased to exist since Braid, in 1843, gave to mesmerism and fluidism the decisive blow that killed them forever."

Such is Dr. Bottey's opinion, but such was *not* Braid's. He said: "I long believed in the identity of the phenomena produced by my method and by that of the believers in mesmerism. . . . I still believe at least in the *analogy* of the actions exercised upon the nervous

[1] Dr. J. Bottey, "Le Magnétisme Animal," etc., p. 1. Paris, 1884.

system"—a very just remark. "Nevertheless, judging from what the magnetizers declare that they produce, in certain cases, there seems to be sufficient difference to regard hypnotism and mesmerism as two distinct agents."[1]

Braid, therefore, has killed nothing, and it would perhaps be well if writers would read him before they assign him any part to play.

Let us proceed to the facts:

Instead of entering into details upon the question of rapport, which would require a separate volume, let us simply point out a few facts which prove the insufficiency of the two psychic causes mentioned above, to explain the phenomena of rapport.

In a person sunk in the *magnetic sleep* the sense of touch presents peculiarities that are quite astonishing. There are many shades of difference in the phenomenon, but we may consider it in its simplest and most definite form; to verify it we shall have but to select a subject that has been magnetized by one person only, and that many times, for this phenomenon is seldom manifested in a first or a second seance.

The subject *feels and takes kindly* the touch of his magnetizer. If extranes touch him, either of two results may follow, according to the state the subject is in: either

1. The touch *will cause him visible annoyance*, which may be so great as to produce a paroxysm; or

2. He *will not feel it at all.*

In the former case, it is not necessary that the touch be direct; touch his clothes, pillow, bed-covering, bed, chair, etc., and though the subject does not see the act, he will shudder, start and complain of the unpleasant sensation. I have made many experiments with a view to eliminate the influence of imagination, and am fully convinced that the phenomenon is real. Besides, it was noticed long ago by Puységur. Sometimes this *elective anæsthesia* is so pronounced that the subject cannot endure even the presence of an individual though the latter be some yards distant from him. But we may suppose that in this case olfactive sensations have some influence. In other cases he will endure the presence of a person even alongside him, but only on condition that the person shall not touch him either directly or indirectly. In this phenomenon there is a regular scale of sensibility: some subjects are influenced only by direct contact, others are influenced at the distance of two or three inches, others at the distance of several yards. I have not noticed any difference with respect to covered or exposed parts of the body; when the touch is disagreeable it is so whether the body is touched directly or through the clothing, only the effect is perhaps a little more obnoxious when one touches a

[1] J. Braid, "Neurypnology." [The quotation is from Brown-Séquard's French translation of the work, p. 27.]

garment that comes in close contact with the skin than when one touches, for example, the hem of a long robe; but the difference is neither constant nor certain.

I anticipate the objections of observers who will bring forward the fact that in some subjects, those of little sensibility, this phenomenon does not occur; that with others, in light somnambulism, the touch of a third person simply awakens the subject; finally, that with others only the first contact gives the subject a shock and that thereafter there is no effect. But there are a good many subjects on whom the experiment can be made successfully.

A physician of my acquaintance, refusing to believe in this phenomenon, once asked me to exhibit it to him. The experiment was made on a young woman whom he knew well, and who was magnetized by me for the fifth time. Her eyes were blindfolded and we stationed ourselves behind her, touching with one finger her hair or her back, according as the doctor indicated by signs. She never once made a mistake in telling which of us two had touched her; indeed, the thing was visible, for there was a reflex movement of repulsion when she was touched by other than me.

There is a physical action, then; but of what sort?

It is of two kinds—1, pathological; 2, physiological.

1. A person that is ill—that is to say, disequilibrated, suffering, and debilitated—re-acts upon the sensitive subject by disturbing her molecular equilibrium, by communicating to her his suffering by influence, or by depriving her of a part of her general molecular energy.

2. A person in good health, but extrane, acts less strongly, as a rule; his touch is not so disagreeable, but is more or less so on account of the difference between his dynamic state and that produced or communicated to the subject by the magnetizer. We are unable to state definitely wherein this difference consists, but we must needs accept it, even outside of magnetism.

If we do not perceive it in the normal state, that does not prove that it does not exist; we do not see the stars by day, though they are ever shining with the same luster. With respect to this matter, the somnambule is an exceedingly sensitive apparatus that is influenced by causes which in the normal state are insignificant.

In the second case—to wit, when the subject feels not at all the touch of the extrane—the following experiment can be made: Instead of touching directly, one may touch with a pencil, for example. If one were to touch directly, as with a finger, differences of temperature, etc., might be supposed to indicate to the subject who it was that touched her. But that supposition has no weight in the case of indirect contact. But now, in spite of that, the subject will feel the magnetizer's pencil, and will not feel the same pencil when it is held by the hand of a third person.

I beg the opponents of magnetism to reflect upon this experiment. It may be varied in several ways. The subject does not feel the pencil, but let the magnetizer touch the hand of the person holding it, and now it is felt again. Nay, more. Let us take, instead of the pencil, a long rod, and let the magnetizer grasp it first at the distance of five, then of ten, finally of twenty-five inches. The pressure of the rod and its contact with the skin of the subject will become more and more confused, more and more uncertain, till at last at the distance of some yards, according to the force of the individual physical action and the subject's sensibility, the latter will feel nothing. Nevertheless the mechanical pressure is ever the same!

Is it imagination that does this? Is it faith? Explain this experiment to me without physical action, and I will renounce magnetism; but not till then.

There are several other evidences of physical action, but this one will suffice for the present. It proves that *molecular dynamic differences pass beyond the surface of the body;* that a certain vibratory tonic movement peculiar to a given organism is propagated beyond its periphery, and can influence the subject so definitely, so palpably, that there is a real action.

There is, then, an individual physical action. The hypnotizers may make as much sport of that as they wish: "He laughs best who laughs last."

Personal dynamic action is one of the causes of rapport. The subject is insensible, but he feels better than ever the hand of his magnetizer. He is deaf, but he hears better than ever his magnetizer's voice. And this it is that, with other things, constitutes rapport.

The fourth and last agent remains—mental suggestion.

The magnetizer's organism, already active by its very presence, becomes more active when, in the dynamic mass that constitutes his personality, there is developed by concentration of thought and tension of will a center of force, strengthening the invisible but most real bond that unites the two organisms.

And now, lest the reader should think we are leading him into a world of fancy, let us glance at the sum of the phenomena common to the two.

In *hypnotic* states these agents are inactive, for in hypnotism there is no rapport; but in magnetic states they manifest themselves in every possible degree. In most instances the first of the four agents (the subject's expectant attention) suffices to explain the facts. This explanation is made more complete by the concurrence of the second agent: ordinary suggestions are associated with the magnetizing processes and the attitude, gestures, etc., of the magnetizer. In a few cases physical action becomes evident. In fine, exceptionally (perhaps once in several hundred cases), mental suggestion overrules all

other influences, and then only is the theory of the *Voluntists* confirmed.

But those who, lightly dismissing the facts, deny physical action and mental suggestion, simply prove one or other of two things: either that they have not studied the question sufficiently—*i. e.*, have not experimented on a great number of persons; or that they are incapable of making delicate experiments. But I forgot—there is a third class—*bona-fide* observers, capable and familiar with the results of experiment, but who have preconceived opinions.

They wear colored spectacles, and for them all things are of the color of their glasses. The result is often ludicrous. I will give three instances: First, the case of a distinguished *savant* who, in order not to accept physical action, concèdes mental suggestion; then the case of a very ingenious but very skeptical analyst, who, unwilling to recognize a physical action, admits mental suggestion and second sight; finally, an excellent observer and discreet innovator who, in his efforts to dispute both physical action and mental suggestion, in spite of himself demonstrates them both, and besides gives the weight of his authority to an utterly præter-scientific opinion.

Let us begin with the last. The question is about Braid. Dr. Bottey, in whose eyes thought-transference is "only a piece of jugglery having its place in the domain of charlatanism," is right, however, when he says that "the only fault one can find with Braid is, that he wished to make his discovery promote the doctrines of phrenology." But Mr. Bottey does not know that it is just the phrenhypnotic studies of Braid that prove thought-transference.

The matter stands thus: Dr. Gall conceived a theory, based apparently on experiment, and in which is some truth, but which in many respects runs counter to the data of physiology, and is entirely wrong in its details. According to this theory, the whole gray matter of the brain is divided into 27 small regions, called *organs*, which are the seats of the several faculties.

Thus, according to Gall, we have in the brain a special organ for Industry, one for Friendship, Quarrelsomeness, Theft, Self-esteem, Metaphysic Penetration, Veneration (the same which at La Salpêtrière determines somnambulism: *pressure* on the vertex), and so on.

Several magnetizers amused themselves with practicing *phrenomagnetism*, *i. e.*, applying magnetism to the phrenology of Gall, Spurzheim, and other craniologists. They acted by contact, pressing upon a point on the cranium corresponding to some phrenological organ, and thus sometimes obtaining in sensitive subjects a manifestation of the corresponding sentiments, dispositions, or ideas.

Braid tried to verify their assertions, and had such success that he was quite surprised at the result. Every few pages of his book he reverts to this subject, and it is highly instructive to see him at the

same time enthused and embarrassed by the strangeness of these phenomena.

In truth, it was a little too much for a mind so positive as his, especially when the man had got it into his head that all hypnotic phenomena result from fatigue of the visual organs. The thing, nevertheless, was true. Braid doubts, experiments again, raises every possible objection; but the reality remains, mysterious, but undeniable. The subject steals a ring if you press on the organ of Theft; shamefaced, he gives it back if you press on the organ of Conscientiousness; begins to pray when you touch Veneration, and fights his magnetizer if the latter bears a little heavily on Combativeness, and so on. Nay, more. Some subjects do not need to be touched; by simply pointing his finger at an organ Braid got nearly the same result. Certain individual differences were noticed: one person could act better than another, and always the best operator is *the one that knows more about phrenology.* Braid, ever more and more embarrassed, experiments on *forty-five* persons one after another, hardly any of whom had any notion of phrenology, and who, therefore, could not simulate. He substituted in place of the finger a glass rod, glass being a bad conductor of electricity and magnetism (!), and then, in place of the glass rod, he used a cork. But the results were the same, the subjects still underwent the action of the organ that was touched!

What was to be done? Physical action was deemed impossible, *à fortiori* mental action. So Braid contrives a highly ingenious but quite gratuitous theory: he supposes a sympathic correspondence between certain points of the scalp and the expression of certain states of mind.

At length, *seventeen years later*, he recognized a certain action upon the subject's intelligence, produced by contact, but was unable to account fully for so many successes obtained.

As for us, while we admit that there were several influences at work in Braid's experiments, we do not hesitate to say that the latter demonstrate a physical action of the magnetizer (whether direct or through the glass rod), and above all that they demonstrate in a very remarkable way the fact of mental suggestion.

All the details given by Braid as to his mode of operation and the state of the subjects with whom his experiments were successful, confirm our view. Braid was practicing magnetism as Monsieur Jourdain wrote prose.

The second observer is Morin. His whole book, a very interesting one, is devoted to a refutation of the "fluid" theory and of the hypothesis of any physical action whatever, but it confirms the facts of *mental suggestion* and even of *vision at a distance.* We will return to this point when we come to speak of theories, for Morin gives a *theory* of mental suggestion.

The third is Bertrand. I am reluctant to find fault with this eminent observer. Like Braid, Bertrand was led simply by a sincere love of truth, and had he had evidence sufficiently strong to meet his requirements, he no doubt would have been quick to recognize a physical action, no matter what the cost in the scientific world. But he had only negative results. Twice, however, he was much embarrassed; once when he was obliged to sign the report of Du Potet's experiments made at the Hôtel-Dieu in presence of Husson and several other physicians, and which went to prove action at a distance. He had signed the document, and then retracted his signature, not without reason; for Mr. Husson, who was not as familiar as Bertrand was with the suggestion theory of the magnetizers, had not taken all the needed precautions. It was Bertrand's ill-luck to call for a new experiment, for that confirmed Du Potet's theory rather than his own. But at all events he was within his right as a skeptical observer; he was seeking evidence that could not be questioned.

On another occasion—but let us hear Bertrand himself:

"I have seen (he says)[1] a somnambule (Mrs. Chevalier) whom I did not magnetize, but whose treatment I had long been observing, and upon whom the person that magnetized her had acquired an extraordinary influence. He could at will deprive her of any one of her senses, making her for a moment blind, dumb, deaf, etc.; could paralyze a portion of her body, or even throw her into a state of perfect lethargy, which ceased only when the magnetizer was pleased to bring her to herself again *by means of a peculiar gesture. This latter fact is the more remarkable because the somnambule was absolutely deprived of the use of her senses,* as I often had occasion to verify. (A witness one day, to make sure of the somnambule's insensibility, pinched her so hard as to cut out with his nails a small portion of flesh, so producing a bleeding wound which she perceived on awaking, and which for some time caused her to suffer.) There was nothing that could give her notice of the moment when the accustomed sign was to be given."

There Bertrand is mistaken. General insensibility though verified objectively in every way, is in no wise inconsistent with even very great sensibility with respect to excitations *coming from the magnetizer.*

Apart from cases of very profound paralytic aideia (which are very rare) and from certain active ecstatic states wherein the subject ceases *momentarily* to hear and to sense his magnetizer, he always does sense him, and that very clearly too, even at a distance, despite the general anæsthesia. He feels the gesture made anear, even while he is sleeping naturally, without ever a suspicion of the magnetizer's presence. Consequently, the fact cited proves only the *individualiza-*

[1] See the details in Husson's report, also in Morin, and in Bertrand, "Du Magn.," p. 259. See also Du Potet, "Expériences Publiques sur le Magnétisme Animal," etc. Paris, 1821.

tion of the sensibility, and not mental suggestion, nor direct physical action. This appears from the further details following :

"This sign consisted in a rapid movement inward of the outstretched hand (consequently there was a current of air). At this sign she started and came to herself ; but usually one sign was not enough ; many signs had to be made one after another, and at each there would be a start, a commotion of her whole body, as though she had received a powerful galvanic charge ; after four or five shocks she would open her eyes, sit up, and come to herself."

Experiments for producing paralysis of any one sense, purely by means of gestures, are rather easy to make. This I demonstrated upon four subjects to the Warsaw Medical Society in 1881.

They do not suffice to demonstrate mental action, nor even physical action of the hand, but they prove the existence of *ideorganic associations* produced by habit, between a sign and an organic state. The experiment is more conclusive when it is performed on a person in his natural sleep, *whom you never have magnetized*, who is not expecting the magnetizer, and whom you magnetize without contact. I once made this experiment under favorable conditions, and was successful. But here again mental action is not proven, if one acts as I did, by making passes at but a little distance, for with sensitive subjects air-movements many times repeated before the subject's face may produce somnambulism without the intervention of special physical action.

On this point Bertrand remarks :

"I found it always impossible by a simple act of my will to make the *waking* patient lose consciousness [as we have seen, this phenomenon does occur, but it is very rare], and when I made the sign *without any act of will*, I produced the same effect as though I had willed to act ; so that my will, *per se*, was without action while I sought to act upon the patient in the waking state ; *but it was not so* when she was in somnambulism or in paralysis, for then *my will of itself sufficed* to make her come to herself [as for me, I never have been able to awaken a somnambule by a simple act of will, at least, not under strict conditions, *i. e.*, under conditions excluding involuntary habitual suggestion. It would seem that in this respect individuals differ]. Still the latter result, it must be confessed, was not as clear as the former, for, as though to prevent accidents that might result *the somnambule was never left more than three or four minutes in unconsciousness*, it was difficult, in so short a time, to make any conclusive experiments."

Of course ; and it seems to me that Bertrand is self-illusioned with regard to his mental action ; that the somnambule, accustomed to sleep only three or four minutes, would have awaked of her own accord. (See p. 20, *supra*.) Bertrand, however, declares (though at the same time himself raising some objections) that in order to convince himself he made the following experiment :

"I placed myself in a part of the chamber where I was hidden by a corner of the mantelpiece. I repeated seven times (when I made the gesture anear the patient, she usually came to herself at the third or fourth)—I seven times repeated the customary gesture while she was unconscious, and seven times she felt at the same instant the shocks (*secousses*) that this gesture is wont to produce; then she came to herself completely. According to what was told me, the shocks were in number the same as my gestures; they took place at the same moment with my gestures, and the awaking came progressively, as when I stood close by her; in a word, nothing is wanting to this observation."

On the contrary, there is wanting to it the certainty that the patient could not *hear* these gestures, or *feel* the currents of air they occasioned.

A strange fact, but one repeated every day in works on hypnotism: Bertrand, who was so exacting when judging the experiments of others, and who did not believe in the magnetic fluid, does not seem very scrupulous in his own experiments upon so complex a question.

He is even astonished to find that the signs or gestures that always produced the desired effect in the state of somnambulism and while the somnambule did not see them, were insufficient in the waking state. That, again, was an effect of ideorganic association. The somnambule was trained in somnambulism, and not in the waking state; consequently, the associations formed in that state could not spring up again in a state totally different. They were related to a special organic state as follows:

Sign	a	*plus*	Somn.	=	Effect	a′	*plus*	Somn.
"	b	"	"	=	"	b′	"	"
"	c	"	"	=	"	c′	"	"
"	d	"	"	=	"	d′	"	"

and that does not mean that

Sign	a	*plus*	Waking	=	Effect	a′	*plus*	Waking.
"	b	"	"	=	"	b′	"	"
"	c	"	"	=	"	c′	"	"
"	d	"	"	=	"	d′	"	"

for there is no continuity between complete somnambulism and waking. But the signs used in the waking state may have influence in somnambulism, for *there is* continuity between waking and somnambulism—the somnambule remembers things happening to him in the normal state.

This complex ideorganic association may apply equally and solely to distinct *phases* of the sleep. Thus it is that at La Salpêtrière catalepsy is obtained by opening the eyes of the subject, lethargy by closing the eyes, somnambulism by friction on the top of the head. These are mere accidental associations that have no scientific value, and which have only brought confusion into the domain of hypnotism

and the magnetic sleep, where already there was confusion enough. Observers, confident of the exactitude of their researches, have made it their business to find the three states where they did not exist, and have sometimes succeeded—*with suggestionable subjects*. Proceeding on the same principle, one might produce lethargy by pressure on the vertex, catalepsy by occlusion of the eyelids, and somnambulism by friction—on the ankle. It is time to make an end of illusions that have already produced a lot of valueless observations.

I have just said that I never succeeded in awakening a subject by simple mental suggestion. That phenomenon, however, was verified by the academic commission of 1826.

"At an agreed signal, given by Mr. Fouquier, Mr. Foissac, *whose presence was unknown to Cazot*, awakened the latter, as he had endormed him, *by the force of his will alone*, despite the questions the company were addressing to the somnambule with the sole purpose of keeping from him all knowledge of the instant at which he was to be awakened. . . .

"September 10, at 7 o'clock in the evening, the commission met at Mr. Itard's to continue their experiments on Cazot. The latter was in the sitting-room and a conversation was opened with him, and kept up till half-past seven, the moment when Mr. Foissac, who arrived after him and had remained in the antechamber, separated from him by two locked doors, and distant from him twelve feet, began to magnetize him. Three minutes after, Cazot said: 'I believe Mr. Foissac is here, for I feel dazed.' In eight minutes he was completely asleep. . . .

"Though the commission could not have any doubt as to the real action produced by the magnetism upon Cazot, even unbeknown to him, we wished to have one more proof nevertheless. The commission therefore went to Mr. Bourdois's study, Oct. 5, at noon, at which hour Cazot came there with his child. Mr. Foissac had been invited for half-past twelve, and arrived at the hour named (the time when Cazot withdrew to the parlor) without any communication with us. He was told, however, that Cazot was sitting on a sofa six feet distant from a closed door, and that the commission wished him to endorm the subject and to awaken him at that distance, he being in the parlor and Cazot in the study.

"At thirty-seven minutes past twelve, while Cazot was engaged in the conversation that we were carrying on, and examining the pictures that adorn the study, Mr. Foissac began his magnetic manœuvres, and we observed that at the end of four minutes Cazot was winking slightly, that he appeared restless; finally, that he fell asleep in *nine* minutes."[1]

Other similar experiments were made by the commission, and were equally successful, but they were conducted under less stringent conditions. Hence, it is needless to quote them.

As regards simultaneous will-transmission and thought-transmission, experiments of that sort were less successful.

[1] This narrative appears to be inconsistent with regard to the locations of Foissac and Cazot.—*Translator*.

"Mr. Guéneau wrote on a bit of paper the following words: 'Go sit on a stool that is in front of the piano.' Mr. de Geslin, making this will possess him wholly, bade the somnambule do what he mentally required of her. She arose from her place, and going in front of the clock said, 'It is half-past nine o'clock.' Mr. de Geslin told her that was not what he had asked. Then she went into the neighboring chamber; again she was told that she was mistaken, so she went back to her place. The next act willed was that she should scratch her forehead: she held out her right hand, but did not perform the desired movement. [It is always wrong to tell the subject that an experiment is to be made, for then emotion awakens her partly, *i. e.*, causes her to pass into an active state—*active polyideia*—and then she reflects too much, and tries to *divine* what is demanded of her, instead of submitting passively to influence. When, under such conditions, the subject is mistaken twice in succession, it is best to suspend the experiment, and to make the sleep a little deeper by the aid of a few passes before the face.] The will is that she sit down at the piano, and she goes to a window six feet away from the instrument. The magnetizer complains that she does not do what is enjoined on her by his thought; she rises, and *changes chairs*. We ask that when Mr. de Geslin lifts his hand she shall lift hers, and keep it raised till the magnetizer's hand is lowered. She raises her hand, and it remains motionless, not falling till five minutes after Mr. de Geslin has lowered his hand."

After these unsuccessful experiments, the commission declared that thought-transference had not been verified, but admits the fact of will-action at a distance. That was the opposite of what Bertrand held, for he believed that there is no will-action at a distance, but that the subject can divine the will of the operator by a *communication of thoughts*. That was rather curious hair-splitting, but we must add that Bertrand had in mind action of will *directly upon the organs of the subject* that are to be put in motion, and that is what he denied, while he admitted the fact of thought-communication, and consequently the possibility of a movement that is ordered being executed, if the subject perceives our *thought* and is willing to conform to our desires.

The commission reached the following conclusions with regard to mental action:

"When once we put a person in the magnetic sleep we do not always need to have recourse to contact and passes to magnetize him again. We can *not only act upon the magnetized person*, but we can put him fully in somnambulism and take him out of it *unbeknown to him*, while we are *out of his sight, some distance away, with doors between him and us*." ("Report of the Academy of Medicine," June 28, 1831.)

The report was signed by Messrs. Bourdois de la Motte (President), Fouquier, Guéneau de Mussy, Guersent, Husson (Secretary), Itard, J. J. Leroux, Marc, Thillaye. Messrs. Double and Magendie, having been unable to be present at the experiments, thought they ought not to sign.

CHAPTER VII.

ACTION UNBEKNOWN TO THE SUBJECT AND AGAINST HIS WILL.

THUS will-action unbeknown to the subject has been verified by an academic commission, but that does not prevent Mr. Bernheim from pronouncing the following judgment in a memoir addressed to Mr. Paul Janet:

"There is not a magnetizer in existence; there is no magnetic fluid. Neither Donato nor Hansen possesses any special hypnotic powers. The sleep produced does not depend on the hypnotizer, but on the subject; it is his own faith that endorms him; no one *can be hypnotized against his will, if he withstands the injunction.* I am happy to join you in assuring the public against all the chimerical fears that a false interpretation of facts might engender."[1]

The public is re-assured; but I am astonished that so eminent an observer could bring together so many inexactitudes in the compass of a few lines.

We may set aside the question of a special fluid, for a fluid is not necessary for an explanation of the facts; we would simply remark that those who have believed in a fluid have always regarded it as a general, not an individual property, presenting only some differences of degree.

"The sleep produced does not depend on the hypnotizer." On the hypnotizer, no; on the magnetizer, yes; that is to say, it does depend on those who, instead of being simply water-bottle stopples, employ their own bodies, their minds, and their wills in the act of hypnotization.

"It is the subject's own faith that endorms him." Have frogs, lobsters, ducks, hens, guinea-pigs the same faith in magnetism that Donato's subjects have?

"No one can be hypnotized against his will, if he withstand the injunction." Nevertheless I have many a time endormed persons that resisted with all their might. Mr. Bernheim is doubly mistaken here, for in most cases this phenomenon can be explained by his suggestional theory, without any direct influence, physical or psychical. There is not even any need to cite the facts of somnambulism produced at a distance, by a direct physical or psychic action.

Ideoplasty may be two-fold—conscious and unconscious. There are persons who in all sincerity declare that they are free from a given prejudice, but who, nevertheless, are influenced by it involuntarily. There is a conscious submission and an unconscious. Provided a subject has sensibility, if you suggest sleep to him that idea may realize sleep despite his opposition.

[1] Bernheim, "De la Suggestion dans l'État Hypnotique," p. 13. Paris, 1884.

The same is to be said of other ideas suggested.

After all, is it wise to cut short in half a dozen words a delicate question that one has not studied sufficiently? That seems to be the fashion nowadays. Here is the author of a book in other respects highly interesting, who says: "The question of thought-reading, of lucidity, of second-sight, is decided once for all."[1]

By whom decided? It would no doubt be no easy thing to say. When one is in such a situation 'twere best he should say, "I have not studied that question;" or, "My studies have yielded me only negative results;" or, "The results I have obtained do not authorize me to decide the question;" but not, "This thing does not exist, that thing is false, because I do not believe in it."

Let us now look at the facts:

1. Mr. S. had a somnambule, Miss X., who was also his mistress. She is at his house, sitting at a table; he is walking about the rooms. Suddenly he sees in the court-yard another young woman coming, and he wants above all things to prevent the women from meeting. Without any long reflection, while still walking, he makes a gesture behind Miss X.'s head, and she forthwith falls asleep, and enters the state of paralytic aideia. He then receives the other woman and talks with her in presence of Miss X., who notices nothing. He did not awaken her till after the other was gone, then he awakened her with one puff of breath, and so rapidly that she did not even know she had been endormed. Mr. S. was still walking about the room.

This fact proves neither physical action of gestures nor mental action of the will, but it does prove that one may be endormed unbeknown to himself. Miss X. was exceptionally sensitive, not to the more refined influences (mental suggestion did not succeed with her), but as concerns the *rapidity* of the phenomena. The impression of an hypnotizing gesture (auditive and tactile) produced sleep by ideoplasty, that is, by an ideorganic association based on habitude, before she had time to think about it.

I knew this person myself and I even made on her a similar experiment:

2. Not having been magnetized in a long while by Mr. S., she believed she had lost sensibility, and one day, in society, she told me she now felt so strong that she would like to try and magnetize me. I agreed for the fun of the thing, and let her have her way. Delighted because I consented, she seized my thumbs and fixed my gaze. To humor her the more I pretended to be overpowered by sleep; then suddenly I opened my eyes and fixed her gaze, intending to endorm her, and she was asleep after a few seconds. We experimented on her for at least three quarters of an hour. Then I resumed my position before her, awakened her with a puff of breath, and continued my pretended sleep. Believing me to be really endormed, she began to clap her hands in triumph, and could not understand why everyone

[1] Cullère, "Magnétisme et Hypnotisme," p. 239. Paris, 1886.

burst out laughing. She would not believe it was herself that was the sleeper.

3. A girl of 14 years was magnetized by me five or six times; she was highly sensitive, though less so than the preceding subject (hyp. exp., insensibility and contracture of the finger, whereas in the other the whole arm was contractured); in very good health (as was the other, too); she was magnetized only for the sake of some experiments designed to convince an acquaintance of mine, a physician. The only effect of these seances was that she slept a little longer in the night in natural sleep, and that magnetism made her prettier—so at least thought her girl friends. But her companions persuaded her to believe that if she should go on letting herself be endormed she would lose her will-power, and she would not be allowed to marry her cousin, whom she loved—as one loves at 14 years. In short, my somnambule refused to obey me, without giving any reasons. She did not wish to be magnetized any more. She was entreated, ordered even, not to be whimsical, but in vain.

"And you are not afraid that I shall endorm you in spite of yourself?"

"Oh, no, for I won't even sit by you."

I was asked to try, and her parents authorized me to make the experiment, angry as they were at the *disobedience* of their daughter.

I then took a handkerchief that she had left on the table and threw it into her lap, saying:

"Well, now 'tis done. You will be asleep in five minutes." "That will have no effect whatever on me," she said. But all the same she hastened away to avoid my gaze. "No use in running away, you will come back of your own accord."

Half an hour later she returned in somnambulism.

Consequently one can be endormed "against his will" and though he "withstands the injunction." But here ideoplasty plays again the principal part.

I might cite three or four others facts of the same sort—skeptics themselves asking me to make the attempt to overcome their resistance and incredulity. *Credulousness without sensibility is of no avail; incredulity is no hindrance where sensibility exists.* The will may retard the action, but it can only retard. Most of those who think themselves hypnotizable are not, and some of those who hardly suspect themselves of sensibility may be hypnotized without difficulty.

Here is a narrative of occurrences that took place in France; it has been published over and over again. The matter came before the courts of law, and all the facts have been verified.

4. "March 31, 1865, came to the hamlet of Guiols a mendicant. He was about 25 years of age; was crippled in both legs. He begged hospitality of one H., who lived in the hamlet with his daughter. She was 26 years old, and her moral character was of the best. The beggarman, whose name was Castellan, pretending to be deaf and dumb, gave them to understand by signs that he was hungry, and he was bid to supper. During the meal he acted strangely, and so attracted the attention of his hosts; he would not let his glass be filled again

without first making over it and on his own face the sign of the cross. During the evening he signified that he was able to write. Then he wrote the following phrases: 'I am the Son of God; I come from Heaven and my name is Our Lord; for you see my little miracles, and later you shall see greater ones. Do not fear me at all, I am sent from God.' Then he offered to remove the film that overspread the eye of a woman then present. He pretended that he knew the future and predicted that war would break out in six months.

"These absurd actions made an impression on those present, and Josephine H. *was particularly stirred by them.* She slept all dressed, out of fear of the beggarman. The latter spent the night in the hayloft, and on the morrow, after he had breakfasted, quit the hamlet. Soon he returned, after having made sure that Josephine would be alone the whole day. He found her busied with household cares, and for a while conversed with her by signs. The forenoon was spent by Castellan in exerting upon the young woman all his fascination. A witness declares that *while she leaned over* the fire on the hearth, Castellan, bent over her, kept making on her back *circular signs* and the sign of the cross; *at those times her eyes were wan.* At noon they sat at table together. Hardly was the meal begun, when Castellan made a gesture as though to throw something into Josephine's spoon. Immediately the girl fainted. Castellan seized her, took her to her bed, and committed the uttermost outrages upon her. Josephine *was conscious of what took place;* but, *restrained by an irresistible force,* she could not make any movement, nor utter a cry, though *her will protested* against the assault committed upon her. Evidently she was in lethargy [in the state of fascination rather]. Having come to herself again, she did not cease to be under the power of Castellan, and at 4 o'clock P. M., when the man was going away from the hamlet, the wretched girl, drawn by a mysterious influence, which *she strove in vain to withstand,* left her father's house and blindly followed this beggarman, *toward whom she had feelings only of fear and loathing.* They passed the night in a hayloft, and on the morrow directed their steps toward Collobrières. One Mr. Sauteron met them in a wood and took them to his house. Castellan told him that he had abducted the young woman after having won her favors by device. Josephine, too, told him of her misfortune, adding that in her despair she had wished to drown herself. April 3, Castellan, followed by the girl, stopped at the house of a Mr. Coudroyer, farmer. Josephine ceased not to lament and deplore the unfortunate situation in which she was held by the irresistible power of this man. 'Bring the strongest and tallest woman,' said she; 'you will see if Castellan will not cause her to fall.' [The poor girl judged from her own impressions. Not more than about 5 persons in 100 are capable of being brought under such an influence, that is to say, unless they have been already hypnotized.] Josephine, dreading outrages that she feared might yet be perpetrated upon her, asked that she might be allowed to sleep in a neighboring house. Castellan came up to her at the moment when she was about to go, and seized her round the hips; *she fainted.* Then, though according to the testimony of witnesses she was like one dead, she was seen, by order of Castellan, to go up the steps of the stairway, counting them without a mistake, then laughing convulsively. It was found that she was at the time completely endormed.

"The next day, April 4th, she fell into a state like that of simple insanity (somnambulic delirium). She was out of her head and refused all food. She invoked God and the Virgin by turns. Castellan, wishing to give a new proof of his ascendancy over her, ordered her to go all round the room on her knees, and she obeyed. Touched by the sorrows of the wretched girl, provoked by the boldness with which her seducer abused his power over her, the inmates of the house drove the beggar away, despite his resistance. Hardly was he outside the door when Josephine *dropped to the floor as if dead.* Castellan was called back; he made sundry signs over her and restored to her the use of her senses. On the next day they went away together. The people dared not prevent Josephine from following the man. Suddenly they saw her coming back on the run. Castellan had fallen in with some hunters, and while he talked with them she took flight. With tears, she begged that they would hide her, that they would rescue her from that influence. She was taken back to her father's house, and since then she seems not to have full use of her reason." [That was quite natural; for with highly sensitive persons who are not thoroughly *demagnetized*[1] a nervous derangement persists for a good while. If they be thoroughly demagnetized the effect of the magnetism must *in all cases* be beneficial.]

"Castellan was arrested April 14. He had already been convicted on a correctional process (*correctionnellement*). Nature appears to have gifted him with very extraordinary magnetic power. [Everybody can magnetize, but there are differences both in the degree and in the nature of the action.] To that cause is to be attributed the mysterious influence he possessed over Josephine [to that cause in part only, for ideoplasty also acted a part], whose constitution lent itself marvelously well to magnetism, as appeared from sundry experiments made upon her by physicians. Castellan admitted that it was by magnetic passes that he produced the fainting fit that preceded the rape. He even confessed that twice he had intimacy with her while she was neither endormed nor in the fainting fit, though she was incapable of giving free consent to his criminal acts. The relations he had with her the second night they spent at Capelude were under different conditions, for on that occasion Josephine had no consciousness of the criminal act of which she was the victim [*paralytic aideia*], and it was Castellan himself that told her in the morning. On two other occasions the conditions were the same.

"On his trial, Castellan exhibited the utmost coolness and audacity. He specially paraded his magnetic powers. He had the impudence to offer to give proof of his skill in an experiment on the President of the court. While undergoing examination by the Procureur Impérial he went further, for by the fixedness of his gaze he threatened to magnetize that officer, and the latter had to require him to lower his eyes.

"Josephine, since she was taken from under the influence of this man, has nearly recovered her reason. In her deposition before the court she says: 'He exercised such power over me by his gestures and his passes that several times I fell in a dead faint. He might do with me then as he would. I know what things I suffered; but I could neither speak nor act, and I underwent the most cruel tortures.'

[1] I beg the reader to take this word in its empiric sense, apart from all theory; I cannot here enter upon explanatory details.

"Three physicians, Drs. Hériart, Poulet and Théus, were summoned to enlighten the jury as to the effects of magnetism. By their declarations they corroborated the conclusions of Drs. Auban and Roux (of Toulon). Castellan was condemned to twelve years of hard labor."[1]

"Extraordinary as these facts may appear," adds Mr. Liégeois to this narrative; "strange as seems the power exercised by Castellan over his victim, we must not regard this as a unique occurrence. I could, I dare say, find among the clientage of Dr. Liébeault not one only, but ten persons, that under the conditions given would be as powerless to resist criminal assaults as Josephine H. was. The facts developed are of great importance."[2]

Now we see why Mesmer insisted on not divulging the methods of obtaining somnambulism. He states the reasons himself: "Since my method of treating and observing disease came into practice in different parts of France, several persons, whether from indiscreet zeal or from a vanity that is out of place, have, without any regard for the reserves and the precautions that I judged necessary, given a premature publicity to the effects, and above all to the explanation of this crisis-sleep; *I know that abuses have resulted from this*, and I see with pain old-time prejudices coming back with big strides."[3]

In the foregoing cases the subject was aware of the magnetizer's intention, or at least of his presence. But this is in no wise essential. A person in a deep natural sleep, who never has seen the magnetizer and who has no thought of his presence, may be subjected to the influence of his passes and of his will, may be put in the somnambulic state, execute the magnetizer's orders, and wake again on the morrow, remembering absolutely nothing, not even in another period of somnambulism, not even under the influence of another magnetizer.

Still, I make haste to add that such cases must, of necessity, be exceedingly infrequent—for they require not only an exceptional hypnotic sensibility, but also a sleep accompanied by *complete insensibility*—and that while magnetism may produce such serious effects, it at the same time supplies the means of guarding against them. Only it has to be remembered that *hypnotism*, which cannot produce these effects, is but an imitation of magnetism.

Let us return to the facts:

5. I was attending a lady patient who was not easily endormed. Once coming to her house a little late, I found her sleeping her natural sleep over a tiresome novel. I endormed her magnetically, left her as usual for a quarter of an hour in paralytic aideia, then held con-

[1] Dr. P. Despine, "Psychologie Naturelle," vol. i., p. 586. Paris, 1868.

[2] Liégeois, "De la Suggestion Hypnotique," p. 48. Paris, 1884. I notice with surprise that in the new edition of his work Dr. Bernheim cites the same narrative, without perceiving that it contradicts his opinions.

[3] F. A. Mesmer, "Mémoire," new edition, with notes by Dr. Picher Grandchamp, p. 56. Paris, 1826.

versation with her in somnambulism; at last, as my time was short, I awakened her.

"Ah, so you are come," she said. "Well, endorm me quick, for my legs are paining me."

"But I have already endormed you, and you have no more pain."

"That is true; it seems to me that I do not suffer now."

But she would not believe that she had already been magnetized.

Another time she was worse. The pains were excruciating, and I was summoned by telegraph. I was away from home, and did not call on the patient till near midnight. I found her out of her mind, raving, groaning, and writhing in pain. I spoke to her; she made no answer. I then laid my hand upon her head, and endormed her within five minutes at the longest. *She always fell asleep more readily when she did not know I was present.* (There was a peculiar individual cause for this, not easily explained here.) The pain ceased instantly, the fever grew less by degrees; I gave her the order to sleep quietly the whole night, and left her. The next morning she was much surprised to find she had slept so well, and only from her husband did she learn that I had come and endormed her.

Finally, I have often endormed patients in a fit of insanity—a more difficult thing, because, unable to recognize the magnetizer, they resist with all their might; but by acting at first from a distance and then coming gradually nearer, one can always attain the end with *patients sufficiently sensitive, that one has endormed before.* As the fit of insanity usually ceases in the magnetic sleep, if the patient is then awakened he is surprised to see us.

6. I myself had occasion lately to endorm an insane woman, absolutely unconscious, having no suspicion of what I was about to do, and who had never been hypnotized. The patient, a woman named Fier (excited melancholia, mania of persecution, thoughts of suicide, mutism), was under the care of Mr. Auguste Voisin at La Salpêtrière. June 29, Mr. Voisin requested me to examine with the hypnoscope a number of his patients. They were brought to me, and I made my notes. When the turn of the patient referred to came, the woman attendant told me that it would be difficult to fetch her, for she was strapped in an armchair, and she could not be brought to me save by carrying her in the chair. So I went to the compartment for violent patients and found a woman of some 45 years, whose face and whose fetid breath betokened inanition. She refused all food, and had taken almost nothing for eight days. A rational word or sign was not to be got from her, and as she had made two attempts to hang herself, it had been necessary to put her in the camisole or strait waistcoat, and to strap her down. I had the camisole taken off and applied the hypnoscope. On pricking her finger with a pin I thought I observed a diminution of sensibility, judging from the weakness of the reflex movements, and, without more ado, *I laid my hand upon her head with the intention of endorming her.* After three or four minutes her eyelids fell and she slept. She replied to me rationally, making signs with the head. I ordered her to sleep till I should come again, and went to apprise Mr. Voisin, who was much pleased with this result, for he was beginning to be troubled about the patient's state.

Half an hour afterward, we, Mr. Voisin and myself, found her still in somnambulism. It was proposed to move her into her bed. I said that she was able to go herself. She was unstrapped from the chair, and I ordered her to rise. She rose and bent forward, but her legs were fixed where she stood. They were stiff. A slight massage removed the stiffness, and, assisted by us, the patient crossed the court to go to her bed. From that moment forth the improvement was noticeable from day to day. She began to speak, to eat and to sleep quietly of nights. For the first few days I tried to keep her nearly all the time in somnambulism, and, in fact, the sleep was interrupted only now and then by the return of the fit of insanity. She had no recollection either of this first magnetization or of the period of derangement. She is still in the hospital, for as yet there can be no certitude of a definitive cure, but she is perfectly rational and does sewing in the workroom. This observation is worthy of a detailed account, but at present I wish only to prove that an insane person can be endormed without any expressed suggestion.

7. And here is an instance to prove that it is possible to endorm an insane patient *in spite of his opposition.* I take it from a memorable observation of Mr. Voisin: "June 1.—The agitation had not ceased. Mr. Voisin wanted to hypnotize her; she *showed fight, spat in his face;* he succeeded only with difficulty. The sleep was deep, lasted twenty-five minutes. In the afternoon and all the next day she was more calm."[1]

Consequently, it is inexact to say that "No one can be hypnotized against his will, if he withstand the injunction." In the new edition of his book, Mr. Bernheim reproduces the same assertion. But I find this at the end of the volume:

"Before applying the suggestional therapeutic, here are the rules I consider myself bound to observe, and which every physician must observe, to safeguard his conscience and his professional honor:

"*First, never to endorm any subject without his formal consent,*" etc.

It is possible, then, to endorm him without his formal consent?

In view of the importance of this matter, I will cite a few more evidences of real action, physical or psychic, exercised *unbeknown* to the subject.

8. "March 15, 1826, Mr. J. Dupotet brought together at Mr. Bouillet's (No. 4 Dragon Street) several persons, to enable them to witness some of the phenomena of magnetism and somnambulism. Mr. Petit, primary instructor (*instituteur primaire*) at Athis, near Fromenteau, who in 1818 had been cured by Mr. Dupotet, by means of the magnetic treatment, of several deposits,[2] and who, having then become a somnambule, has ever since shown much sensibility to magnetism, kindly consented to offer himself for the following experiments: . . . .

"Mr. Dupotet, having bandaged the somnambule's eyes, repeatedly held his fingers pointed toward him, at the distance of about two feet; immediately there appeared in the hands and the arms, toward

[1] Voisin, "Etude sur l'Hypnotisme et sur les Suggestions chez les Aliénés," p. 7. Paris, 1884.

[2] *Dépôts.*

which the action was directed, a violent contraction. . . . Mr. Bourdin tried to produce the same effects; he, too, obtained them, but less promptly, and in a milder form. These experiments were repeated to satiety. . . . While Mr. Petit was playing piquet [in somnambulism] Mr. Dupotet, at the instance of Mr. Ribes, brought his hand, from behind, near his [Petit's] elbow: the contraction previously observed took place anew. Then, by request of Mr. Bourdois, he magnetized him from behind, still at the distance of more than a foot, with the intention of awakening him; the keenness of the somnambule's interest in the game countered this action, so that instead of awakening him, it incommoded and annoyed him; several times he raised his hand to the back of his head, as though he had a pain there; at last he fell into a doze that seemed to be a rather light natural sleep, and some one having spoken to him in that state, he awoke with a bound, as it were.

"A few minutes afterward Mr. Dupotet, still behind him and at some distance, put him again in the magnetic sleep, and the experiments began anew. Mr. Bourdois directed his hand toward one of the somnambule's arms, intending to make it perform a certain movement. After a few moments there was produced in the arm, and especially in the hand, a very marked agitation, which became so violent that Mr. Dupotet felt called upon to allay it.

"Mr. Bouillet, lest there should rest any shadow of doubt upon the reality of a physical action exercised at will, proposed to blindfold Mr. Petit with as many bandages as anyone might wish, and to act upon him in that state. So his face was wrapped about down to the nostrils with several cravats, the chink left on each side of the nose was stuffed with gloves, and the whole was then covered with a black cravat, falling like a veil down to the neck. Then we began once more to make all sorts of experiments on action from a distance, and the same movements were in every case manifested in the parts of the somnambule's body toward which the hand or the foot was pointed. After these new tests, Mr. Dupotet having taken off the bandages from Mr. Petit, played a game of écarté with him, to occupy his attention and to amuse him. The somnambule played with the same skill and still won. He played with such ardor that he was insensible to the influence of Mr. Bourdois, who tried in vain to act upon him from behind and to make him execute an order of his will. The play ended, the somnambule rose, walked across the parlor, pushing aside the chairs that were in his way, and went and sat apart to rest himself at a distance from the quidnuncs and experimenters that had wearied him. There Mr. Dupotet, who was several feet away from him, awakened him; but apparently the awakening was not complete, for a few moments afterward, while in the company of the Count de Gestas, he dozed, and a new effort had to be made to awaken him fully. When awake, he had no recollection of what had taken place during his sleep."

The minutes were signed by Messrs. Bourdin, M. D., member of the Academy, President of the Commission appointed to investigate magnetism; Ribes, M. D., member of the Academy of Medicine; the Count de Gestas, Deputy; Deleuze, Assistant Naturalist of the Jardin des Plantes (he did not arrive till the middle of the seance); Raynal, ex-Inspector-General of the University; Raynal, Jr., student of law; Lachevardière, printer; Binet, Professor of Mathematics in

the Ste. Barbe College; Bouillet, Professor of Philosophy in the same college, and Corbin, Assistant Professor of Rhetoric in the College of Lyons.[1]

9. In another seance, January 26, 1826, after having awakened Mr. Petit, Mr. Dupotet endormed him again at the request of several persons. He was then distant from Mr. Dupotet the whole length of the parlor, had his back turned to him, and was talking with one of the company. Present at this experiment were, with others, Mr. Ampère, of the Academy of Sciences, and Messrs. Adelon and Ribes, of the Academy of Medicine.[2]

10. All means have been employed against magnetism—even lying. A certain young woman named Samson was cured by Mr. Dupotet. Mr. Récarmier, in order to destroy the effect of this cure, bethought him to announce in full Academy that Miss Samson had since re-entered the Hotel Dieu *and there died.* Mr. Dupotet having met her in the street, took her to the house of Mr. Husson, Secretary of the Academic Commission, where everybody recognized her. The only thing to be done was to verify by new experiments the phenomena she had presented six years before, but she refused obstinately, and her refusal suggested to the members of the Commission the idea of trying the action of magnetism *in spite of the subject.* "I felt that this was a sort of indirect challenge," says Mr. Dupotet, "and I made ready to honor it. So I began to act upon her unbeknown to her, and then came a sort of struggle between her and me, in which she was seen to put forth all her efforts to keep herself aloof from my influence. She showed violent agitation, and this, after being suspended during a moment of exhaustion and absolute immobility, reappeared with most curious characters. She, in fact, presented a most striking image of the ancient Sibyls; controlled as she was by an irresistible force, she sprang suddenly from her armchair as those prophetesses from their tripods; nothing could divert her from this frenetic enthusiasm. [In magnetizing a subject against his will we always produce a sort of somnambulic delirium; the subject talks incessantly, or else is seized by nervous spasms—in the latter case he must not be awakened till he is calm.] After having exhausted every kind of physical excitation, it occurred to us to address to her aloud the most aggravating speeches—such as women feel most keenly; but her complete impassibility plainly showed that she heard nothing. As for me, standing at a certain distance from her, I spoke to her and made myself heard; I touched her and she was conscious of my touch; it was the same when there was question of awakening her; the others made a noise, one might say a most deafening uproar, in trying to rouse her, but it was in vain; then it was that, receiving from them a request to awaken her, all that was needed for me to succeed instantly was a simple act of my will."[3] (The subject who is in the magnetic sleep cannot be awakened save by the one who has endormed him, or who has been able to enter into rapport with him—another difference between magnetism and hypnotism, for the hypnotized subject can be awakened by anybody.)

Readers will perhaps be surprised that I quote magnetizers as one quotes scientific observers. It is true that I would not have done so

[1] "Le Propagateur du Magnétisme Animal," etc., p. 32. Paris, 1827.

[2] *Id.*, p. 30.

[3] *Id.*, p. 52.

ten years ago; but since then I have found out that magnetizers are at least as worthy of confidence as hypnotizers, and that if there are among them some credulous folk who have mal-observed and misinterpreted certain extraordinary phenomena, there are among hypnotizers, too, many who have mal-observed and misinterpreted certain very ordinary ones.

Incomplete instruction is sometimes preferable to science sophisticated by prejudices.

That the will takes part in magnetizing action can no longer be denied. True, when one employs passes, the eyes, verbal suggestion, etc., simultaneously with will power, the latter may be superfluous, or at least its action is doubtful. In most cases it is certainly useless, for the subjects influence themselves, or else the physical action of the hand dispenses with mental action. But one subject that is exceptionally sensitive suffices to prove the existence of this action, provided you can influence him without passes, without the eye (*sans regard*), without words, and without involuntary suggestion. As we eliminate, one after another, the accessory agents, we come upon the true one. Hear what is said on this head by a contemporary *Voluntist*, Dr. Perronet, taking care to reduce to their true value the author's generalizations:

11. "I have employed several processes," says he, "to obtain catalepsy artificially. Whatever the processes—magnetic passes or odd gestures made for the purpose of discharging an alleged fluid—they all have the same results; whatever value they have they derive from theories or from beliefs subjectively preconceived.

"Eschewing, therefore, all mimic ceremony, I was content to say, 'Sleep!' and forthwith the catalepsy appeared. Nay, I dispensed with that formula, trifling though it was; I concentrated all the power of my will within itself, I stripped it of every symbol whether mimic or phonic; I condensed it, so to speak, with a view to obtain the magnetic sleep in a predisposed person; the latter without being prepared by any previous conversation, by any sign, or by any act that might physiologically account for the fact, stopped short in the middle of a phrase, his members and his eyes fixed in cataleptic immobility and insensibility.

"'Why do you sleep? Come, awake,' said I to the subject, in order to intimate to the persons present the true cause of the crisis. 'You know well that I cannot awake,' answered the subject. 'Why?' 'Because you want me to sleep.' 'What you say is false; how do you know that I want you to sleep? Did I tell you to go to sleep?' 'You did not tell me; you say the contrary to tease me, but I know well that you want me to sleep.' 'What must be done to awaken you?' 'Will it you.'

"I willed the subject to awake, as I had willed him to sleep, that is to say, without manifesting outwardly by gesture or word the essence of my willing; the awaking was effected rapidly.

"I succeeded often with this experiment, and hence I infer that the will of the operator is the sole, or at least the preponderant, instrument

in producing artificial catalepsy; that in a word the stage business of passes, cabalistic gestures, commanding or mysterious looks (*regards*) is a supererogation. [The author forgets that all subjects are not mentally suggestionable.] Though I would not deny utterly the utility of passes, etc., I hold that they derive their power from the direction given by the will; that being backed by a firm, energetic will, they concur in making the experiment successful, but not without the will-power: in short, that will-power alone, unaided by any outward act, suffices to produce catalepsy artificially.

"The same is to be said of all the acts performed by the operator with a view to obtain such or such a result. *The will alone gives efficacy to the act.* Thus, for example, in virtue of *a priori* ideas, I have believed that pressure exerted by me on the pit of the stomach of a catalepsied person will produce manifestations of ecstatic enjoyment; the result corroborated my hypothesis. I asked a friend of mine to exert the pressure instead of me. At once clonic spasms that were subjectively looked for by me, agitated the subject, and ceased the moment I myself touched the person that was exerting the pressure; they began again when my contact was interrupted.

"Another time, influenced by a theory of the movement of fluids in living organisms, I believed that on touching the feet of a catalepsied subject, I should produce in him sudden contractures, and that I could make these disappear by touching the head and the feet simultaneously. Everything happened as I had anticipated, but that is no proof that the physiological effects are indissolubly connected with these manipulations; any other processes whatever would have succeeded, provided I had believed in their efficacy.

"The formula is of small account; will-force is all. Here we may ponder that word of the gospel: 'The letter killeth, the spirit *maketh alive.*'"[1]

Thanks to the impulse given to scientific research by the Society of Physiological Psychology, of which Mr. Charcot is President, these old discoveries of the magnetizers have been corroborated by many savants, and now men are zealously collecting well-observed cases with a view to draw therefrom theoretic conclusions. The magnetizers, and in particular the *Voluntists*, have been treated with derision long enough; it is time now to make the amend of honor to them, and to give *cuique suum.* Let us see what has been published by members of the society upon the part played by the will in magnetic experiments.

In striving to determine under what conditions, and by what influence sleep was produced in the case of Mrs. B., Mr. Peter Janet finds:

a. That fixation of gaze (*fixation du regard*) was useless.

b. That pressing the hand favored the sleep a little and made it deeper.

c. That the production [of sleep] was still more prompt if, instead of simply pressing the hand, the thumb was laid exactly against the thumb of the subject; but

[1] Perronet, "Du Magnétisme Animal," pp. 15-17. Paris, 1884.

d. That none of these processes has any influence *if the thought is wandering, and if the will does not intervene.*

Let us make haste to say that we have to do with a monograph, not with a general theory. Unfortunately, this difference is too oft forgotten. It is truly astonishing that physiologists that know how to generalize prudently when there is question of ordinary researches, lose their head when they deal with hypnotism. And not only lose their head, but believe themselves dispensed from all circumspection with regard to facts affirmed by magnetizers. "Magnetizers have observed this or that in a thousand cases, therefore it is fudge; I have seen this or that in Mr. X. or Miss Z., therefore hypnotized persons behave thus and so." Hypnotism is taken to be synonymous with magnetism, and, lo! there you have a generalized observation, put forward under the observer's authority, but which positively has no scientific value, not even an individual value, for the reason that the individual's peculiarities are not pointed out, and that it is not said whether the sleep was procured by a shining button or by passes. Hand a magnetizer that is familiar with experimentation Heidenhain's unfortunate little book, for example, and he will simply shrug his shoulders; and yet Heidenhain is an eminent physiologist. There is a good deal more truth in Mr. Dupotet's exaggerations than in the scientific observations of Mr. Heidenhain. I should be embarrassed were I asked to point to a single page in Heidenhain that could be accepted without reservation. Think you that when he writes a treatise on hypnotism or "self-styled magnetism," he at least was careful to read Braid? Not a bit of it, nor Mesmer either! Yet, if the question were the action of cocaine, or of narceine, he would, no doubt, read up his predecessors. Such is the *Fluch der bösen That,* as the Germans say. Science has spurned and ridiculed magnetism; magnetism now sends the curse back home.

So then, without generalizing, for it is certain that in most cases we shall not be able to demonstrate the mental action of the will, let us see what has been observed by unbiased experimenters in *some privileged subjects:*

12. "One day Mr. Gibert was holding Mrs. B.'s hand to endorm her; but he was visibly preoccupied and thinking of something other than the business in hand; sleep did not come at all. This experiment, repeated by me many a time in various ways, has shown us [says Mr. Janet] that to endorm Mrs. B. *one must concentrate his thought strongly upon the order to go to sleep* that one gives, and that *the more the thought of the operator is distracted the more difficult it is to produce sleep.* This influence of the operator's thought, extraordinary as it may seem, is here absolutely predominant, so that in fact *it may take the place of all other influences.* If you press Mrs. B.'s hand without any thought of endorming her, you do not produce sleep; on the other hand if you think of endorming her without pressing her hand, you will succeed perfectly. So we left Mrs. B. seated at the lower end of the

room; then, without touching her or saying a word, Mr. Gibert, who was at the other end, held his thought upon willing to make her sleep; in three minutes lethargic sleep appeared. I repeated the same experiment many times with the utmost ease; all that was needed was that (remaining, it is true, in the same room) I should think strongly upon my will to endorm her. Once I succeeded in endorming her even *in spite of herself* and though she was in great agitation, but it required five minutes of effort. It has often happened that while waiting for Mr. Gibert, I would remain by Mrs. B., in the same attitude of meditation, in the same silence, without any thought of endorming her, and then the sleep would not even begin. On the other hand, so soon as, without any change of attitude, I thought upon the order to her to sleep, the eyes of the subject would become set and soon lethargy began. In the second place, if the attitude of the persons present had suggested the sleep, I cannot explain why only the person that had produced it by thought, could, in the lethargy, produce the characteristic phenomena of contracture and attraction."[1] [That, too, is a character of the magnetic sleep that does not exist in hypnotism. Consequently, they who confound the two phenomena and after having obtained the magnetic sleep, without knowing it, say that a pressure, or a mechanical excitation, produces this or that, are mistaken, for *pressure*, or *excitation*, as such, produces absolutely no effect. The literature of hypnotism is full of such inexactitudes.]

13. "In the course of the year 1873 [says Mr. Richet], being then *interne* of the Beaujon Hospital, I made many experiments in somnambulism. In only one of the subjects endormed by me was I able to produce somnambulism at a distance. [At present I quote only the experiments that were made in the same room, and which prove only will-action.] It was a young married woman of some 25 years, who, *being at first with difficulty accessible to sleep*, at last, from having been trained to the process, could be endormed with very great facility. At first I endormed her by passes; then by touching her hand; at last simply by entering the ward in which she was. Mornings, when I entered the ward with Professor Le Fort, chief of my department in the hospital, I would see her at the opposite end of the ward immediately falling asleep. But as I did not wish her to be in that state when Mr. Le Fort should reach her, I would make every effort *mentally to awaken* her, and in fact she always used to awake a few moments before Mr. Le Fort came to her bedside."[2]

14. "The observation I report here [Dr. Héricourt is speaking] dates from the year 1878, and I communicated it at the time to my friend Mr. Charles Richet, who has kept it faithfully and prudently among his papers for reasons easily understood. The case was that of a young woman of 24 years, of Spanish descent, a widow, and mother of a little girl of 5 years. Mrs. D. is small, thin, very brown, has the pilose system greatly developed. The most thorough investigation developed no trace in her of hysteria, whether hereditary or individual. When I tried to produce hypnotism [*magnetism* is meant] in Mrs. D., she never had undergone any experiment of the kind. The first attempt, however, succeeded fully after some twelve minutes spent in gazing at her fixedly and holding her thumbs fast in my

[1] P. Janet, "Notes sur quelques Phénomènes du Somnambulisme." (*Bull. de la Soc. Psych. Phys.*, 1885.)

[2] Ch. Richet, "Un Fait de Somnambulisme à Distance."

hands. In the sequel the same result was obtained by simply gazing at her, or touching her head or her hand for not more than a few seconds; at last, with still less ado, as will presently be seen. The state of Mrs. D. was then from the first moment one of lucid somnambulism; she was fluent in conversation, her intelligence was quick, her sensibility seemed heightened, her memory was remarkable; every image evoked produced an hallucination, but this phenomenon never appeared spontaneously. [The state then was *polyideic*, with tendency to *passive monoideism.*] At the same time there was total insensibility to pain, and the members which were the seat of a very definite muscular superexcitability were put in catalepsy by a simple touch, without modifying in the least the psychic state. [That is a very common phenomenon in magnetism, and it proves: 1—That it is not necessary to open the subject's eyes to produce catalepsy; and, 2—That catalepsy may co-exist with somnambulism, and that, therefore, it is incorrect to regard these two states as distinct *phases.* In general, all classifications based solely on external characters must necessarily be defective, for *all* the external characters may be produced in all hypnotic states and even in the state of waking. Only the *psychic* characters can serve as a basis for a valid classification. Somnambulism is a *cerebral* phenomenon first of all, and therefore we must not seek elsewhere but in the brain the differentiating characters of its phases. We may only say, for example, *cataleptic* or simply *paralytic* aideia, or polyideia, to indicate the cases where the members are limp, or where they keep the posture given them.] At the awaking, which I produced by drawing my finger over the upper lids, the memory of what had taken place was wholly lost; but in the second state it made an unbroken chain of the facts of her waking state and those of her state of sleep.

"As I have said, I endormed Mrs. D. with greater facility each succeeding day. In fact, after a fortnight or so of this special training, I no longer needed, in order to obtain that result, either contact or the power of the eye. I had only *to will*, using no sort of gesture whatever that might betray my intention. If she were engaged in animated conversation with a number of persons while I was in some corner in an attitude of the utmost indifference, I would soon see her, as I willed, trying to ward off the sleep that was coming upon her, and at last succumbing, or taking up again the thread of her thoughts, accordingly as I either continued or ceased to apply my thought to the result to be obtained. And I might even gaze fixedly on my subject, hold her fast by the thumbs or the wrists, and make all imaginable passes of the sort used by professional magnetizers, yet if it was not my will to endorm her she remained wide awake and conscious of my powerlessness."[1]

15. Finally, a fourth observation of this kind was communicated to the Society by Mr. Glay. It was made by Mr. Desart, sometime *interne* of the Paris hospitals, and was published in the *Tribune Médicale* (May 16 and 30, 1875): "The case was that of a girl of 14 years whom Mr. Desart was called, in 1869, to treat for a serious hysteric affection—paralysis of sight and smell, perversion of taste, loss of power of movement and of sensibility in the right arm and both legs, œsophagism, rachialgia, suicidal tendency. Mr. Desart tells how he came to think of endorming her. The spasm of the œsophagus was

[1] J. Héricourt, *Bull. de la Soc. de Psych. Physiol.*, 1885.

such that she had to be fed with a tube; but swayed as she was by the thought of suicide, she every time had a fierce struggle with us to prevent the introduction of food. It took three of us, often four, to overcome her resistance. After the food was introduced, the patient would strive in every way to bring on vomiting, would keep expectorating and shouting for hours at a time.

"Her parents, whose intelligence was below the average, and who were full of prejudices, were opposed to the employment of narcotics or any agent capable of quieting her. In these circumstances the patient was failing rapidly and giving us much anxiety. The struggle for the introduction of nourishment lasted from early in June till the end of October. Then it was that I proposed to the parents a method I had for some time had in mind—magnetic sleep. All my knowledge of magnetism was limited to a few recollections of what I had seen when I was an *interne* under Aran. I had often seen that physician endorm an hysteriac, and I said to myself that I might doubtless greatly improve the condition of Miss J. if I could make sure of her digesting her food, by producing after each meal a state of sleep, or at least a sufficient calm."

So Mr. Desart tried to endorm her by means of passes, as he had seen Aran do. He was successful and fed his patient without difficulty. In trying to discover how the sleep was produced he was led to observe the following phenomena:

"I observed," he says, "that when, in making passes, I allowed myself to be distracted by the parents' conversation, I never was able to produce sufficiently deep sleep, even after trying for a long time. So, then, the intervention of my will had to count for a good deal. But was that sufficient without the aid of any outward manifestation? That was what I wished to know. I therefore came one day, before the hour set for her awaking, and, without looking at the patient, without making any gesture, I mentally ordered her to awake. I was obeyed instantly. As I had willed, the delirium and the outcries began. I then sat before the fire, my back to the bed of the patient, whose face was turned toward the door of the chamber, and talked with the persons present, without appearing to pay any attention to Miss J.'s cries. Then, at a given moment, no one noticing what was going on in my mind, I gave the *mental order* to sleep, and sleep followed. More than one hundred times was the experiment made, and modified in various ways; the order used to be given at a sign made to me by Dr. X., and the effect was always produced. One day I arrived when the patient was awake and in full delirium; she continued her outcries and her agitation regardless of my presence. So I sat down and awaited the signal from Dr. X. That given and the mental order formulated, the patient grew quiet and fell asleep. 'You knew that I was in the room for some time?' 'No, sir! I knew of your presence only when I felt sleep coming upon me. Then I was conscious that you were in front of the fire.'"[1]

This last remark explains how mental transmission, following a concentration of thought, may simulate vision. At the same time, with the act of will, some sensations are also transmitted, and produce in

[1] E. Glay, "À propos d'une Observation de Sommeil provoqué à Distance." (*Bull. Soc. P. P.* 1885.)

the mind of the subject a visual image of the operator and his surroundings—a veridical hallucination, as Mr. Frederic Myers well calls it.

Oftener still the will-action, though not transmitted as such, simply strengthens the *physical action* of the magnetism, which can be exerted without this special concentration; and there are all possible degrees —purely ideoplastic action, ideoplastic and physical, purely physical and physical and mental. The first (purely ideoplastic action) is the most common, the last (action physical and mental) the rarest. Physical action holds the middle place as regards frequency, but it comes in so often, or rather is so often perceptible, that it is easily verified.

I wish to speak of this latter category of *mediate will-transmission* before I pass on to the more extraordinary phenomena of suggestion.

When your hand acts upon a waking patient, the concurrence of ideoplasty is always to be supposed, but one can experiment *on sleeping infants*, and in that case it is not easy, especially if it is a first experiment, to show that imagination is the sole cause of the action. Such experiment does not demonstrate (at least not directly) mental action of the will, but it does demonstrate *physical* action, and the former is not comprehensible without the latter. I mention these experiments with the more pleasure because they have brought about the conversion of an old sinner, a man highly respected and of great worth—I mean Dr. Liébeault, apostle of the theory of suggestion and father of the hypnotic school at Nancy. For many years he, like everybody, confounded hypnotism with magnetism, and rejected the theory of physical action. It was the *little children* that converted him, and, singularly enough, a suggestion from Mr. Bernheim made the conversion complete.

"We sought," writes Mr. Liébeault, "to repeat our experiments upon a still younger child, *according to the advice given by Professor Bernheim.* And at bottom this is the same mode of experimenting long ago employed with advantage by Dupotet and Dumont upon three juvenile subjects, with a purely physiological end in view, though they acted at a distance, in this differing from us. A little child, Louise Meyer, one year old, was presented to us in such condition as we wanted. For four weeks the child had cried night and day, and in spite of the care bestowed upon her by a very excellent physician, no change for the better had yet appeared. To us she seemed to have continuous colic pains, the result of obstinate constipation. Now and then, perhaps, she would sleep five or six minutes at a time. During one of these naps, *consequently unbeknown to the babe,* we prolonged that state and kept her twenty minutes under our hands, till there was a sign of awaking. From that moment, as by enchantment, she cried no more, slept even a good part of the night, and was brought back to us the following day quiet and beginning to have stools. Three seances during the following days, but without her sleeping, completed the cure."

This fact may seem extraordinary to a physician who knows only drugs, but for magnetizers it is an everyday matter, and I have verified it over and over again. And there is no need to suppose that a one-year old baby has read the works of Dupotet, or attended one of Mr. Donato's seances, to acquire the robust *faith* that is indispensable for hypnotic action: all the same, it can be cured.

Mr. Liébeault cites forty-five similar observations, and, like an honest man and one that knows how to observe, he concludes thus: "In view of the curative effects we have just recounted, we are led to admit a direct action of the neurility—[but why of the neurility alone? The whole body acts physically; nerve-action and mind-action do but emphasize and confirm that action. Among the facts I have verified is this, that the speediness of the curative action depends largely upon *the agreeable impressions received just before by the magnetizer*, but it is always exercised more or less when an ailing organism is magnetized by a man that is in sound health, even though his will be not specially intense]—we are led to admit a direct action transmitted from man to man, and possessing this essential, irreducible, *sui-generis* character, that it can re-establish the physiological functionment of organs. A nerve-undulation was, in the cases of all our patients, transmitted from us to their nervous systems, and consequently, though in what way we know not, gave a beneficial impulse to the diseased organs. Though as regards magnetism I am a psychologist, and for a long time have been opposed to the theory of the fluid by externation,[1] I can no longer deny that certain phenomena are due to the action of one organism on another, without any conscious intervention of the subject under experiment. . . . It were no inconsiderable advance were these two different views both accepted, for they enable us to account for many facts which before seemed inexplicable by either of them alone. . . . In the meantime we invite the true friends of science, those who, being *independent*, do not believe in the infallibility of academicians—we invite them to verify our experiments. The work is easy, and we are sure that they will confirm our conclusions, even as we have confirmed those of the Liège magnetizer, Mr. Longpretz."[2]

These words were written three years ago. Since then not a single savant has tried to verify Mr. Liébeault's assertions. There has been a hundred years of waiting, and we can wait a while longer. Unfortunately, the matter involves a difficulty—that of finding an independent medical man.

Rara avis!

[1] *Du fluide par externation.*

CHAPTER VIII.

DEFERRED MENTAL SUGGESTION.

THE phenomenon next to be considered constitutes a special case of will-transmission—a deferred transmission with time fixed. In reality it is not the transmission that is deferred or retarded, but only the execution of the order given ; the action is mental suggestion " with a long time to run " (*à longue échéance*).[1]

Everybody has heard of deferred mental suggestions with a long time to run ; they have become commonplace. You order an hypnotized or a magnetized subject to perform some act after he awakes—to-morrow, the day after, a week, even some months hence. Awakened, he will have no thought whatever of the matter ; but when the hour comes he will, perforce, carry out your order, knowing neither how nor why the thought has come to him. Generally the subject assimilates the thought, so to speak, and thinks he is acting of his own accord, as if to prove the truth of Spinoza's dictum, that " we know not the causes that determine our actions."

Dr. Gibert has employed mental, as others have employed verbal, suggestion in producing this phenomenon, and he has obtained no less satisfactory results.

Not the least surprising thing in this class of facts, of themselves surprising enough, is, that certain somnambules with whom the transmission of orders to be executed at once is unsuccessful or difficult, are highly susceptible to long-interval suggestions.

To explain this fact as far as it may be explained, we must recall what we have already said about two different unconscious strata—one strong, manifesting itself in somnambulism ; the other weak, overborne by the first, not subject to our direct investigation, but ready at the propitious moment to re-acquire its right to act. Transmission seems to be more easy in this latter stratum, and seems even to take place very often, yet can give us no plain proof of its existence. This is the domain of Leibnitz's " imperceptible sensations." These cannot manifest themselves immediately, but give them the time needed in order to work up into the higher strata, and they will appear at the surface.

" Mental suggestions," says Mr. Janet, " may be given to Mrs. B. in another way, and have quite other success. The result is uncertain when you bid her execute the order immediately, during the sleep ; it is much surer when you mentally order her to execute the order later, some time after awaking."

[1] *Échéance*, the falling due of a promissory note, etc.—*Translator.*

1 "October 8, Mr. Gibert gave a suggestion in this way: without uttering a word, he brought his forehead near that of Mrs. B. during the lethargic sleep [thus it was a state more or less *aideic*], and for a few moments concentrated his thought on the order he gave her. Mrs. B. seemed to experience a painful impression, and uttered groans [as we have seen, p. 90 *supra*, this impression may be so strong as to bring on an attack of hysteria]; in other respects the sleep seemed not in the least disturbed. Mr. Gibert told no one the order he had given, but simply wrote it on a piece of paper which he put in an envelope. The next day I came back to Mrs. B. to see the effect of this suggestion, which was to be executed between 11 and 12 o'clock. At 11:30 the woman showed the greatest agitation, left the kitchen where she had been, entered a room and took away a tumbler; then, overcoming her timidity, she decided to enter the parlor, where I was, and excitedly asked if I had not called her. Upon my replying in the negative, she went away, and kept going up stairs and down several times between the kitchen and parlor, though she brought nothing. That day she did nothing more, for soon she fell into a sleep, being endormed by Mr. Gibert at a distance. During her sleep she said: 'I trembled when I came and asked you if anyone had called me; I had to come—it was rather inconvenient to come with this tray—why am I asked to carry glasses? What was I going to say? Wasn't it that I don't want you to do that?—I was to say something to you on coming.'

"On opening the envelope, I saw that Mr. Gibert had the day before ordered Mrs. B. 'to offer a glass of water to each of those gentlemen.' Here again it must be acknowledged that the experiment was not a complete success. The suggestion was not executed; but can it be denied at least that it was taken in?"

2. "Here is a more significant experiment. October 10, we, Mr. Gibert and I, agreed to make the following suggestion: '*To-morrow at noon lock the doors of the house.*' I wrote the suggestion on a piece of paper, which I kept about me and which I would not show to anyone. Mr. Gibert made the suggestion as before, bringing his forehead near that of Mrs. B. The next day when I arrived, a quarter before 12 o'clock, I found the house barricaded and the door locked. I learned on inquiry that Mrs. B. had just locked it. When I asked why she had done that singular act, she answered: 'I felt much fatigued, and did not wish you to be able to enter in order to endorm me.' Mrs. B. was at the moment much excited. She kept roaming about in the garden, and I saw her pluck a rose and go to the letter-box at the entrance gate. These acts are unimportant, but it is curious to observe that they were just the acts that the evening before we had thought of ordering her to do. But we decided to order another act, that of locking the doors; yet the thought of those other acts doubtless occupied Mr. Gibert's mind while he was giving the order and she too was influenced thereby." Rather in this case the transmission was doubly unconscious; transmission of the unconscious of the first order (in the operator) to the unconscious of the second order (in the subject).

3. "October 13, Mr. Gibert ordered her, still mentally, the next day at noon to take a spread umbrella and twice to go the round of the garden. That next day she was much excited at noon, twice made the round of the garden, but did not spread the umbrella. A little

while afterward I endormed her to quiet her agitation, which was becoming greater and greater. The first words she spoke were these: 'Why did you make me walk round the garden? I looked like a fool. If only the weather were like yesterday's, though. But to-day I should have been a laughing-stock.' It was a very fine day, the day before it rained heavily. She did not wish to spread the umbrella for fear of being laughed at."

In what state (of the subject) were these deferred suggestions possible? We shall soon see; but it is a long story.

In the beginning of the experiments Mrs. B. presented only two quite distinct states: deep sleep (aideia) and light sleep, *i. e.*, somnambulism properly so-called (polyideia, passive or active). The former state was usually characterized by complete muscular immobility (paralytic aideia); the latter by excessive sensibility, with facility of movement, and with intelligence.

These two states *alternated indefinitely*, that is to say, after having manifested a certain intelligent spontaneity, the subject, as though fatigued, relapsed into aideic immobility, passing thence anew into the lucidity of somnambulism. That was a sign of maximum hypnotic sensibility, for at a slightly lower degree the subject does not return again to aideia, but passes little by little from sleep to the waking state, or rests a little while in a state very like normal sleep (with only this difference, that rapport continues), then awakes. This transition may last several hours, but it is always accompanied by sensibility, whereas subjects that are in the state of maximum sensibility *pass to and fro between these two principal states*, without waking of their own accord till they have had a night's natural sleep, and sometimes even they do not come to themselves the following day.

Probably there was between these two principal states an intermediate *monoideic* state of longer or shorter duration.

Not to enter into details, we may affirm, on the basis of Mr. Janet's own account, that not one of the three well-known states—catalepsy, lethargy and somnambulism—as described by Mr. Charcot, existed at this period.

But sometime after, Mr. Janet went to the Salpêtrière to study the hypnotic triad, and took it away in his head, slightly confused (as he himself confessed to me); so he set to work to discover the three phases in Mrs. B. "If these states did not exist in her," said he, "*might not one try to produce them?*" But that was not the work of a moment. Mr. Janet had to be "infinitely persistent," to experiment, to verify; above all as regards the "lethargy," the production of which was a "a very laborious" task. At last he succeeded in *producing* (that is the word) *six* different states.

"New studies undertaken with the same end in view," says Mr.

Janet, "verified the preceding results, complicating them a little, however, I must say." *A little* is, perhaps, not the word.

However that may be, Mrs. B. at that time presented, over and above the three principal phases—catalepsy, lethargy and somnambulism—three intermediate phases, lethargic catalepsy, lethargic somnambulism and somnambulism with the eyes open, or cataleptic somnambulism.

Plainly, the subject, restrained in her natural tendencies, defended herself as she could.

But Mr. Janet, to bring more order into this vicious circle "made the subject go through, in one direction or in the other, the whole series of these states." And then, the subject defended herself so well that she manifested a seventh phase, called by Mr. Janet *lethargic catalepsy;* then an eighth, *somnambulic lethargy* (that is as though we were to speak of a black white), which was added to the lethargic somnambulism already mentioned.

The latter state has special interest for us, for it was in that state that the deferred mental suggestions were given (by bringing the foreheads of the magnetizer and the subject together). These suggestions could not be carried out immediately, but they could be in a subsequent more active phase. It is important that we understand what that phase was.

In *lethargic somnambulism* there is still relaxation of the muscles, as in the deeper state preceding it; there is still insensibility, but already certain moral phenomena come into view which were absent in the preceding state. The subject begins to *dream aloud* (*somnambulic* dreaming, which sometimes deserves to be called somnambulic delirium); he regains sensibility and complains if he is hurt in any way physically, or should he seem not to notice hurts *he will recollect them soon in the state that follows.*

This remark of Mr. Janet's is a very ingenious one, for this is precisely the moment for the latent perceptions of the second order, which await a *more mobile* state (the lucid somnambulism of Mr. Janet) in order to be able to manifest themselves. Once the lucid somnambulism (polyideia) has appeared "new suggestions are nearly impossible."

Lethargic somnambulism, then, is strictly the same state described by me in the case of Mrs. M. as monoideic, only it is a little more advanced, a little more polyideic (dreaming aloud: dreams are always hallucinational), and a little more active (the subject complained of hurts); that is to say, I acted on Mrs. M. in the state of *nascent monoideism*, in which she was more passive, whereas Mr. Janet acted on Mrs. B. in a state of *definite monoideism.* Therefore I was able to act immediately,[1] whereas Messrs. Janet and Gibert were obliged to in-

[1] *I. e.*, to act, *and make the subject act*, immediately.—*Translator.*

fluence the unconscious of the second order, already overborne by the unconscious of the first order, and which, consequently, had to await its turn to be raised to a higher grade.

These distinctions are fine-drawn, I know, but we cannot do without them. But I may remark that it is difficult, if not impossible, to obtain all these gradations in one subject; subjects, in fact, are characterized by predominant tendencies toward such or such a state, and it is enough if, with a little persistence, one can obtain just a glimpse of these flitting phases. Hence, I am not raising objections against Mr. Janet, who is a very conscientious observer; I am only verifying the shades of difference between states.

I myself reached the conviction, by experimenting on Mrs. B., that, with her, immediate suggestions[1] seldom or never came to anything, because a direct mental order[2] *excited* her overmuch and produced a kind of *somnambulic monomania*, which always interferes with immediate transmission. Hence it was that we have seen her bring to an end on the following day, on the occasion of another suggestion that failed, the execution of an order given her by me.

As for the phases, Mr. Janet obtained even a ninth—*somnambulic catalepsy*—and that completed the series for the time being. After that ninth state, the first state came back, and so on. The succession became more and more rapid, till at last it was no longer a somnambule, but a hurdy-gurdy. At first the crank had to be turned—excuse me! —*the thumb had to be pressed* to make the subject pass through all the states in succession, from lethargy to catalepsy, or one had to *blow* upon her eyes to make her traverse them in the reverse order; but later these means were no longer needed, for the subject went like a mill-wheel.

Here, observe, pressing on the thumb takes the place of "pressure on the top of the head," or blowing on the subject; but an air from an opera would have done as well. "The cause of this procession of states is still obscure," says Mr. Janet. For me it is very clear. All the states that have been imagined, or that will yet be imagined, present to us one thing only—*sleep more or less profound.* More or less profound sleep means:

a. Partial paralysis of the brain (polyideia); or
b. Incomplete paralysis of the brain (monoideia);[3] or
c. Total paralysis of the brain (aideia).

But as the paralysis we observe in hypnotism (I use the word in its

[1] *I. e.*, suggestions to be executed immediately.—*Translator.*

[2] *I. e.*, an order to be executed straightway.—*Translator.*

[3] In the original the first two phases of paralysis are called *paralysie partielle*, and *paralysie incomplète*. The difference is that in partial paralysis a *part*, some, of the cerebral organs, or centers, are paralyzed, others not; while in incomplete paralysis *all* the cerebral organs are paralyzed, but not completely.—*Translator.*

broadest sense) is not a strictly pathological paralysis, but a physiological state of inhibition, this inhibition, or relative paralysis, must always be accompanied by an evolution of force,[1] that is to say, by a relative exaltation, which equilibrates it. The sum of the nerve-energy remains about the same, but one portion of the brain loses what another portion wins. Consequently, though the *psychic field* is always more or less narrowed in somnambulism, and even because of this narrowing, the psychic functions may gain in quality what they have lost in quantity.

Every inhibitive cause—and the inhibitory power of a cause does not depend upon that cause solely, but on a relation between it and the field of action and the surroundings for the time being—every inhibitive cause, I say, will make the subject advance from polyideia toward aideia, and every dynamogenic cause will make it advance in the contrary direction.

Now, it must be remembered that the brain is not the only nerve-center of the organism.

The new distribution of the vital energy, the apparition of the *plus* or the *minus*, is seldom restricted to the brain alone; it extends to other centers—cerebellum, bulb, spinal cord, ganglia. If the brain loses, all these are the gainers, and that according to the relations, whether hereditary or acquired, that attach to those centers. Now, by the very nature of this admirable organization of our economy, there exists a certain physiological antagonism between the action of the brain and that of the automatic centers—cerebellum, bulb and spinal cord—and, on the other hand, between the cerebro-spinal system and the ganglionary.

Besides these primary antagonisms, there are partial antagonisms characteristic of the individual or of the moment, and from this we can see the complexity of the phenomena that may result.

Suppose the action of the brain to be for a moment done away (aideic state), then the automatic centers will profit by this: there will be an exaggeration of the reflex actions, as in a decapitated frog. But the vital energy, having left the brain more or less completely, may withdraw into the cerebellum rather than into the cord, and, then, instead of *inanimate* reflex action, so to speak, we shall have a series of coördinated automatic movements, we shall have a somnambulism *exteriorly active*, and more or less intelligent, in proportion to the concurrence yielded by the brain to the cerebellum. Again, if the energy goes chiefly to the cord, it may by preference seek the anterior fasciculi, and in that case there will be an enhancement of contractions (lethargic aideia, or lethargy as defined by Mr. Charcot), with profound and mechanical neuro-muscular excitability that may take the more durable form of general contracture—that is, of tetanic aideia

[1] *Dynamogénie.*

—or the evolution of force (*dynamogénie*) may manifest itself in the posterior fasciculi and give rise to reflex hyperæsthesia, in which the slightest superficial excitations will be enough to bring about contracture (Charcot's somnambulic contracture, which, however, is by no means peculiar to the somnambulic state alone). This hyperæsthesia may be followed by complete anæsthesia, if inhibition should give place to the state of exaltation; and, supposing a like thing to take place in the anterior fasciculi, we shall have, furthermore, complete paralysis with relaxation of the muscles—that is, simply *paralytic* aideia.

Each part of the nervous system—every ganglion, every fasciculus, each cell, one might say, may be excited or paralyzed momentarily; no rigorous order, no regular and inflexible classification of these several *complexus* is to be thought of. *All* the external characters of somnambulism in general—anæsthesia, hyperæsthesia, catalepsy, contracture, neuro-muscular excitability—can be produced in degrees corresponding to the general conditions of the moment, in all hypnotic phases—nay, in the waking state.

Consequently, it is a waste of time to define over-nicely in detail the combinations of the *external signs;* we add one to another pretty much as we please; we modify them, change them about at will, and if there is in these combinations anything essential or fundamental, that surely is the *psychic* state, the state of the brain itself, and that state is just a sleep, more or less deep—polyideia, monoideia, aideia.[1]

On this canvas (with very highly sensitive subjects) you may broider what you will.

Sketch me any state you choose; bring together at random the most contradictory characters; let the sketch be fantastical—a state somnambulo-lethargo-catalepti-tetanic—and I will show it you realized within three days.

If right after any excitation the hypnotic phase changes, that is because the excitation acted either to endorm more profoundly, or to bring the subject nearer to wakefulness, and that natural change carries with it a host of accidental characters that you have impressed upon the subject by passes and on-breathings (*souffles*), the physical action of which you deny; by verbal suggestion, by habitude, by ideorganic association; finally, sometimes by mental suggestion. Thus have Braid and his successors sometimes practiced magnetism unawares and without seeming to do so.

Mr. Janet has done so in perfect good faith, though he still confounds hypnotism with magnetism, calling Mrs. B.'s sleep hypnotic, though she never has been *hypnotized.*

[1] The question of the phases is too complex to be cleared up by a few remarks; nor was it my intention to do so. I wished only to define a few points relating to our main object.

"Inasmuch as mental suggestion," says he, "sufficed to endorm Mrs. B., it must needs also suffice to transfer her from one phase of the sleep to another. The supposition was easily verified. Mrs. B. was in lethargic somnambulism. While making mental suggestion, without touching the subject, I kept thinking simply this: 'I will that you sleep.' In a few moments she was in *somnambulic lethargy* [that is to say, in a sleep a little deeper]. I repeat the same mental order; she sighs, and forthwith is in *lethargy*, then in *cataleptic lethargy*, and every time that I take up that thought again, she thus enters a new state.

"She passes thus through all the phases, and comes back to her first state. One thing to be noted is, that the mental order always made the subject advance in the same direction. She was once more in lethargic somnambulism, and I essayed to make her revert to lucid somnambulism. Instead of thinking 'Sleep on!' I thought 'Awake!'"

In the beginning Mr. Janet did not succeed; by a force of habit that we can understand, the subject passed into a profounder state; but little by little the unconscious grasped her master's thought, and the succession of the phases proceeded according to the unuttered wish of the magnetizer. "The magnetizer's thought, then," concludes the author, "may by an inexplicable influence, directly verifiable, however, make the subject pass through the several phases in either direction."

So, then, here is proof direct that the phases can be elicited mentally, as were the several psychic states in Braid's "phrenhypnotism."

I would not have anyone suppose that my criticism is an attack upon Mr. Janet. In fact, the question is not about Mr. Janet's opinions at all. His conclusions are very moderate, very discreet, and cannot be attacked. I have simply profited by the occasion offered and analyzed the *facts* published by this author—facts which I regard as furnishing the strongest arguments against the schematic tendencies of Mr. Charcot's school. These Mr. Janet has involuntarily reduced *ad absurdum*, while meaning to serve them.

As for his own conclusions, they are as follows:

First, he admonishes the reader that "one must not draw any general conclusion from a monograph;" then he explains himself more clearly: "Some lay great stress upon the phases of hypnotism, and regard them as states entirely distinct from one another; others see in them only phenomena without significance, produced by the operator artificially. The facts that I have stated, and in particular the manner in which they were observed, do not agree with either of these extremes. They show that the three primary states have no such high importance, for we can call forth several other states as well characterized and as lasting. The number of these, I believe, *is*

in no wise fixed; at first I observed six, and later nine. The number of these phases remained the same through some *fifteen seances*, but in the later seances I was forced to recognize the existence of a new state, as yet rather indistinct, but plainly *forming*. . . . No doubt, with more practice on the part of the subject and greater skill on the part of the operator, other states still may be determined."[1]

But neither does Mr. Janet view these phases as merely accidental phenomena, and he is right. A state artificially produced is always a resultant of the operator's personal influences and of the subject's physiological nature or idiosyncrasy. But the more *mobile* the subject (in the Puységurian sense of the word), the more do these first influences prevail. Here is an experiment I made in presence of Mr. Janet and the other gentlemen at Havre: I asked Mr. Janet to mention a state in which catalepsy of the arm is impossible. He instanced one of those lethargic states with complete relaxation of the muscles. Without a word, I seized the arm of the subject (who, however, had not been endormed by me); I raised it, and it fell; thus, no catalepsy. I began again with a little insistence; again the arm dropped, but slowly. I raised it the third time, with intention to see catalepsy make its appearance, and the arm remained outstretched, and retained the position given to it. I was not successful in a second experiment, wherein it was attempted to produce the continuation of movements begun and not belonging[2] to a given phase; but Mr. Janet, too, did not succeed at the first attempt. At last, when Mr. Janet's faith with regard to the value of the phases began to be unsettled, the subject, too, or rather her unconscious, became rattled; states got mixed, were passed over two or three at a bound, so to speak; and I do believe that to-day this whole edifice, so patiently built up, is in ruins for the want of a foundation.

Were these facts not sufficient to make an end once for all of this tangled, idle question, I might add that when Mr. Gibert (who did not believe in the phases) endormed the subject, the phases did not appear. Moral—Beware of mental suggestion!

Is contact necessary for deferred mental suggestion? Hand-contact seems indifferent; contact of the forehead facilitates, perhaps, the inoculation, according to Mr. Gibert. But the interesting fact —observed, as I believed, by me in the case of Mrs. B.—is that "psychic inoculation" seems *painful* to the subject. She always submits to it with difficulty, struggling and re-acting with a sort of convulsion. Then the "psychic virus" becomes, little by little, assimilated, and the subject grows calm. Could the subject tell us

[1] Pierre Janet, "Les Phases Intermédiaires de l'Hypnotisme" (*Rev. Scient.*, May 8, 1886, pp. 577–87).

[2] *Continuation des mouvements commencés et étrangère à une phase donnée. Étrangère* is no doubt a misprint for *étrangers.*—*Translator.*

straightway what has just been inculcated into her? I think not! Her bearing does not betray it, and, indeed, were it otherwise she would be capable of carrying out at once the order given, and that is not the case. Consequently there is reason to believe that the inoculation takes place from the conscious to the *unconscious of the second order;* that the traces impressed[1] are too faint to appear at once upon the scene of the cerebral life, but that they persist and are retained in the lower strata of memory, not to reappear till the moment when the hour associated with them shall have struck. Then the dynamic virus frees itself from the oppression of conscious thoughts that have been keeping it confined in shadow; the suggested thoughts take possession of the psychic field, and bring about a sort of almost somnambulic monomania which struggles for a time with the normal polyideia. Then, sometimes the definiteness of the suggested ideas is effaced in the tussle with the normal state; sometimes they succeed more or less in getting in among the conscious thoughts and in being realized outwardly.[2]

If the struggle is a long one, and the subject, excited, disturbed, irritated, grows more and more absorbed in his monomania, without getting as far as a precise and immediate execution of the order, then what happens is what happened during my stay at Havre—the subject *falls asleep* by automatic psychic influence.

And then calm is restored. The brain takes repose in a transient state of aideia.

CHAPTER IX.

MENTAL SUGGESTION AT A DISTANCE.

THERE remains for us only one more class of facts—that comprising cases of action at a distance. These phenomena surely are the most extraordinary and the hardest to explain. True, when once you grant mental action, *i. e.*, the influence of human thought neighbor to our own, the question of distance becomes secondary. They who are content with mystic notions might even hold that thought, being independent of matter (unfortunately it is not), can act through the distance hence to the moon as well as it can forehead to forehead. But the method of positive science does not allow us to go beyond experience, save step by step. It is well to recall with

[1] *Perçues.*

[2] The many bold and sometimes rather odd metaphors of this paragraph are the author's own.—*Translator.*

regard to this subject the wise words of the "Hippocrates of Magnetism:"

"The impressions," says Deleuze, "produced by objects are fainter in the ratio of the distance at which the objects are situate. The farther we are from an object, the fewer rays of light does it send to our eyes. The sound of a bell is reduced in proportion as we increase our distance, till at last it is no longer perceptible. Impressions made upon somnambules must in like manner be weakened by distance. Hence, from this, that a somnambule feels the action of his magnetizer 20 paces away, it does not follow that he will feel it in like manner at 20,000. . . . These limits are not known; they are far or nigh, according to the measure of the somnambule's sensibility; but there they are, and we must take care not to set them further back than is warranted by decisive experience."[1]

There is still another source of possible error, in view of which we must exercise the utmost discretion, not only as regards a greater or less range, but also with respect to action from a distance in general.

We must needs allow that certain subjects are able to perceive others' thoughts; but we do not yet know how this is done. Now if, as Morin holds, mental suggestion proves only an extraordinary exaltation of the perceptive faculties, that perception may be had at two paces or at twenty in one room, but not through a partition, and completely unbeknown to the subject. Here doubt is quite in place, and we see that the contrary supposition is not to be admitted without sufficient experimental evidence. Hence it is that, having already verified in a way that left no doubt in my mind, mental suggestion from anear, even unbeknown to the subject, I did not feel at all justified in accepting the facts published by Messrs. Gibert and Janet; so I went to Havre to make sure of them. Here, undoubtedly, is the question's core: all depends on action at a distance. We can have no decisive idea of the process of transmission from anigh until we know whether this transference is possible only under conditions of ordinary perception, or whether it can manifest itself even beyond the probable range of our senses. And at the same time the whole theory of magnetism must, of necessity, take a new shape.[2]

But on the other hand it is to be remarked that once we concede transmission from anear, *independent of all normal perception*, the question of distance becomes secondary, inasmuch as action at a kilometer's distance will not surprise us much more than action at the distance of a meter, and that because of the very nature of the phenomenon, which in that case assumes the special character of a

[1] Deleuze, "Hist. Crit. du Magnétisme Animal," i., p. 189. Paris, 1813.

[2] This point is elucidated by Dr. Héricourt in his article "Somnambulisme au dehors de l'Hystérie" (*Rev. Scientifique*, June 28, 1884).

transmission *sui generis*, like telephonic and radiophonic transmission, and independent of direct sense-perception.

Of course Deleuze's reservations still retain their validity, and we must advance slowly, step by step, as experience shall warrant.

Mesmer was familiar with the fact of mental transmission at a distance. As we shall see, he even offers an ingenious theory to account for it, and it is very probable that what gave most offense to his contemporaries—to wit : his breadth of view, his universal fluid, etc.—was attributable, above all, to his profound belief in action at a distance. But just as with regard to somnambulism in general, he thought he must be reticent about this portion of his studies, which he communicated only to a few favored friends under the seal of secrecy. Mesmer generally experimented a good deal more than he wrote, stated his results very briefly, and even the fundamental principles of his teaching, of which a small number of copies was printed, were distributed only among chosen disciples and nearly always under the pledge of secrecy. Consequently we possess very meager details as to what took place in the "chamber of crises," to which the profane were never admitted.

Still, as regards action from a distance, a little distance indeed, but from another room, we are able to quote an interesting experiment, reported by a judicious observer, the Austrian savant Seifert, who at first treated Mesmer as a charlatan, but who afterward, mainly under the influence of the facts I am about to recount, accepted the mesmerizer's theory.

1. The occurrence took place in 1775, at Rochow, Hungary, in an old castle of the Baron Horetzky, of Horka. Mesmer was treating the Baron with magnetism, and at the same time had under his care several other patients who came from the vicinage to consult him. Seifert looked on all this as humbuggery.

One day newspapers were brought, and in one of them was found an account of Mesmer's doings, according to which the magnetizer had produced convulsions in some epileptics that had been apparently cured by the exorcist Gassner, Mesmer being concealed in a neighboring room and there simply making his finger move in the direction of the patients. Seifert arrived at the castle, newspaper in hand, and finds Mesmer surrounded by gentlemen. He asked him if what the paper said was true, and Mesmer confirmed the story. Then Mesmer was asked to give experimental proof of action through a wall. At first he refused, but the company urged him so hard—not without a purpose—that finally he accepted the test. From among the most sensitive of his patients he selected a young Jew, suffering from disease of the chest. He placed him in a room separated from the side drawing-room, in which the experiment was to be made, by a wall two and one-half feet thick. Under these conditions the experiment could not be altogether conclusive, as the subject looked for an experiment of some sort ; but it is interesting because of the peculiar circumstances that we will recount presently.

Mesmer stood three paces away from the wall, while Seifert, as an

observer, stationed himself at the partly open door, so that he might be able to observe both the magnetizer and the patient. This is what he witnessed :

At first Mesmer made, with the index finger of the left hand, several horizontal motions in the supposed direction of the patient. The latter soon began to complain, felt of his sides, and seemed to be suffering. "What ails you?" asked Seifert. "I don't feel well," he answered. Not content with this reply, Seifert demanded a clearer description of what he felt. "I feel," said the Jew, "as if all my inwards were balancing right and left."

In order to avoid asking questions, Seifert told the patient to let him know of any changes he might be sensible of, without waiting to be asked. A few minutes afterward Mesmer moved his finger in an oval. "Now everything is going round in me as in a circle," said the patient. Mesmer then ceased to act, and almost immediately the patient declared that he felt nothing more; and so on. All these declarations agreed fully, not only with the moments of action and the intervals, but also with the sensations that Mesmer wished to to excite.[1]

2. The same author describes another experiment not less extraordinary. Mesmer, as we know, held that the physical transmission is aided by sound, and that sound-waves may be, so to speak, charged with the fluid and may transmit it to a distance. Now, it was customary in the Baron Horetzky's castle for two musicians from time to time to blow a huntsman's horn in a kiosque in the garden. The patients, who were awaiting the coming of Mesmer, and who were separated by several walls from the garden, listened with pleasure to this music. One day Mesmer, wishing to make the experiment, visited the kiosque. Seifert went to the hall where the patients were to see Mesmer. He did not find him, but to his surprise observed that some of the patients, instead of enjoying the music as usual, were becoming uneasy, and even showed more serious nervous symptoms. Seifert ran to look for Mesmer and found him in the kiosque, his right hand holding the flange of the hunting-horn the musician was blowing. He told what had happened; Mesmer smiled as he heard. "I expected that," he said. Then he touched the instrument with his left hand, and lastly let it go entirely, saying: "Now, or presently, the patients will grow quiet." They went back to the hall and found the patients coming to themselves by degrees.[2]

Can we admit the reality of such action? Experiment is needed in order to decide the question. But is there not some analogy between this phenomenon and the phenomena of Bell's radiophone, by means of which a light-ray transmits the voice? Who would have ventured to believe in such a thing ten years ago? It is a fact, nevertheless. And here is another phenomenon that I have observed once only, and which consequently still needs verification :

Mrs. M. was in the magnetic sleep. While awaiting the time of her awaking, I struck a few accords on the piano. Immediately the

[1] Dr. J. Kerner, "Franz Anton Mesmer aus Schwaben," p. 28. Frankfort-on-Main, 1856.

[2] *Id.*, p. 44.

somnambule, who just before was in the state of moderate (*peu profonde*) paralytic aideia, gave signs of attention and seemed to be pleased by the sounds. As she never heard anyone but myself, I wished to ascertain what might be the action of sounds produced by another person. So I motioned to Miss B., and she went to the piano and played the same accords. Mrs. M. gave no sign of sensation. I played again; she heard. Miss B. played once more and *fortissimo;* no action. "You heard me playing?" I asked the somnambule, trying to deceive her. "No," said she; "I did not hear anything."

That is a special case of rapport and probably a very rare one, for usually somnambules more or less distinctly hear music, and singing in particular. Can it be that there is such physical difference between sounds produced by the magnetizer and the same sounds produced by another person? Can it be that sonorous vibrations transmit the personal tonic movement upon which depends the somnambule's perception? That is a matter yet to be studied.

3. Experiments in action at a distance would seem to have been very frequent in France about 1784, for in a pamphlet attributed to the Marquis de Dampierre, we find this:

"The following experiment has been made repeatedly: A highly susceptible person was left with other persons who were in the secret and who tried to occupy her attention. In the meantime she was magnetized unbeknown to her from the adjoining room, and the effect was nearly as prompt and nearly as manifest as though the operator had been nigh. The only difference noted was that, not knowing that she was being magnetized without her co-operation, she at first held herself in check (*se contraignait*), mistaking what she felt for a natural indisposition, and did not cease to resist till the action, bearing upon her with force, put it out of her power to conceal from herself that she was magnetized. One experiment would not have been decisive, so several were made. Results were obtained more or less marked according to the degree of sensibility possessed by the person magnetized."[1]

4. But we find earlier traces still. Action at a distance was successfully tried in the case of the possessed nuns of Loudun:

"Many times the exorcists [*i. e.*, the magnetizers unknown to themselves] called secretly this same nun [Elizabeth Bastard], sometimes mentally and by their thought only, again in a low voice, but without being heard by the persons present. This woman felt herself drawn to the places whence they called her, and suspecting the purpose, lay down upon the floor to withstand her inclination, and nevertheless on these occasions she usually obeyed."[2]

5. Van Helmont, the great physician and great dreamer of the 16th century, must have studied this question, so explicit is he with

[1] "Réflexions Impartiales sur le Magnétisme Animal." Geneva-Paris, 1784.

[2] "Relation de ce qui s'est passé aux Exorcismes en Présence de Monsieur, Frère du Roi," p. 39.

regard to it. He believed that everyone is capable of influencing his fellowmen from a distance, but that generally this force lies dormant in us and oversloughed by "the flesh." If it is to be exercised there must be a certain harmony between the operator and the subject. The latter must be sensitive, and his sensibility must be trained so that, under the influence of the "inner imagination," it may meet the action of the magnetizer half-way. This magic action is felt particularly at the pit of the stomach, for "the sense at the pit of the stomach is more delicate than in the fingers or even in the eyes. Sometimes the subject cannot even bear the laying of one's hand upon that region."[1] The observation that the magnetic action makes itself felt first at the pit of the stomach is an interesting one, and should be considered in the light of Petetin's discoveries and of a recent observation of Dr. Héricourt, who writes: "Mrs. D. declared that whenever I was thinking of her she felt a sharp pain in the præcordial region; in fact, the same pain she felt when the somnambulic seances were protracted, and which decided me to bring them to an end." "Hitherto," says van Helmont,[2] "I have hesitated to unveil a great mystery, namely, that there is in man an energy in virtue of which he can, by his mere will and by his imagination, act outside of himself, and impress a lasting influence upon a very remote object. This one mystery illumines with a sufficient light sundry facts hard to understand, bearing upon the magnetism of all bodies, upon man's mental power, and upon all that has been said regarding man's magic and his mastery of the universe."[3]

This, remember, was written two hundred years ago!

6. The comparison of the sensitive subject with the compass-needle is ever recurring in these old authors. It is justified by the undoubted analogy that subsists between the physical action of a hand and that of the magnet in general;[4] but especially is it justified by the *attractive* action of the magnetizer on the magnetized. This is a very complex

[1] "*Persæbe os stomachi non fert manum oppositam; ibidem esse sensum acutissimum ac præcisum, qui alioqui magis in digitis extremis requiri videbatur.*" J. B. von Helmont, "Opera Omnia," p. 278. Frankfort, 1682. Our author s translation of van Helmont's words is slightly inaccurate. No comparison is made between the "sense at the pit of the stomach" and touch and sight; it is only said that a very acute sense is manifested at *os stomachi*, such sense as under other conditions (*alioqui*) we look for in the finger-tips and the eyes; the pit of the stomach becomes a tact-organ and a visual organ.—*Translator.*

[3] *Ib.* See also "De l'Opinion de van Helmont sur la Cause et les Effets du Magnétisme," by Deleuze, in "Bibl. Magn. Animal," vol i., p. 45, vol. ii., p. 198; and Dr. Ennemoser, "Der Magnetismus nach der allseitigen Beziehung," p. 616. Leipsic, 1819.

[4] This subject I have treated in an article in Polish, "The Magnet and the Hand," which appeared in the scientific magazine *Niwa*, published in 1881 at Warsaw, and of which I was editor.

question, for it assumes many different forms: 1. Attraction by ideoplasty, fascination, imitation of movements. 2. Reflex physical attraction by the approximation of the hand. 3. Direct physical and mental attraction, *i. e.*, attraction without intermediation of ordinary perception, from a distance. The magnetized subject is always drawn toward the operator, seeks him, tends to come nearer to him; hence, the mental suggestion experiment that succeeds most readily is one that makes the subject come to the operator. The subject will always incline toward the magnetizer, and Mr. Janet has observed that, after having endormed Mrs. B. from a distance, he found her head leaning in the direction of his action. But the most striking fact of this kind is recorded by Bruno:

"The phenomenon that surprised me most," he says, "because it was the first that came under my notice, is the one I am about to relate. A young woman 18 or 19 years of age had been, for five or six months, dying of consumption. After three or four days of treatment she slept. Her sleep became very deep in a few days. When I magnetized her, her head leaned toward me; I was obliged to push her back gently in her chair, to prevent her falling on me. As that is a usual effect of sleep I paid no attention to it; after magnetizing her I left her sleeping quietly and went to another patient. But now new trouble: the girl leaned to one side, sometimes fell on her next neighbor, and some one had to be continually holding her up. I had a large armchair provided for her in which she might sleep comfortably. Vain precaution! Her head leaned quite slowly, but by jerks, and all that portion of her body which was not held back by the armchair followed this movement. At last a thought struck me: that her head always leaned toward the side on which I was. I changed my position gradually, and what was my astonishment to find that her head, like a veritable compass-needle, followed the curve I slowly made around her at the distance of five or six feet. It stopped when I stopped, always leaning toward me. . . . In vain I went to a greater distance, the effect was the same. I left the room, went down into the courtyard, placed myself in different directions. I went and placed myself at a very great distance in the angle of a second courtyard of my house, which faces on two intersecting streets; my 'compass' always showed, with the utmost exactitude, the point of the horizon at which I stood. She had to be supported or she would have fallen out of the chair.

"This experiment was very successful when I made it in presence of a physician, to whom I left the choice of the places. After having had me placed at different points outside of the chamber, while he remained in it himself, in order to observe the directions in which the young woman would turn, he proposed to me to go into the street. He himself led me to a corner of the court-yard very far from the house. I had ordered that no one should touch the girl, so that her direction might be seen on our return. As soon as I was in place, the physician went back promptly, and hurried upstairs with all speed. He found the girl had fallen on the floor. I had seated her on a very low chair, telling the attendants to see that her fall should be very gentle, and to assist her in falling by helping her with their arms to

the floor. The direction of her body was not exactly toward my place, the back of the chair having hindered that, but she had fallen to that side. Her sleep was not disturbed by the occurrence. The next day the same physician had some doubts as to the direction of the fall, which did not seem to him to be exactly toward where I had stood, and he was not willing to accept the explanation I had given. So he asked me to repeat the experiment. When I had gone down into the street he desired that I should go around the neighboring house, situated to the west of mine. He went upstairs immediately to observe what might take place. It was agreed between us that the attendants should prevent the girl's falling. He returned in time to witness the prodigy, and it produced conviction in him. I walked very slowly, *always thinking of the girl*, and that without knowing the full importance of that operation. The head of the patient indicated to him perfectly the direction in which I went; he also perceived the action I exerted (*l'action que je fis*) from the position of her body, which was in danger of falling soon. A young woman who was in the custom of assisting her when in this state kept her from falling But soon that was no longer necessary. The girl straightened herself up, and the new direction of her head, which described a curve from east to west, announced my return."[1]

This observation possesses interest for us, for it shows how a physical phenomenon of bodily attraction produced by the mere presence of the magnetizer may be accentuated by the concurrence of mental action. But it is of very rare occurrence, and generally the attraction is purely reflex (sensation of warmth and of air-currents); or, if it be direct, it is exerted only at a very small distance. It is also to be remarked that Bruno's somnambule tolerated the attouchment of a third person, that is to say, there was no hyperæsthesia, properly called. This point is one that we shall not fail to consider from the view-point of theory. Strong attraction is always accompanied by rigidity of the members. It ceases sometimes at the moment of a general contracture, but there is always a tendency to contracture wherever attraction manifests itself. After Bruno, and often without knowing of his researches, several magnetizers have noted the same phenomenon. It is to be regarded as an aid to mental suggestion when one calls to him the subject.

7. "We sometimes," says Dupotet,[2] "find subjects of such mobility, that you may act upon them through partitions or walls at a moment when it is not possible that they should be cognizant of your intention. They sense your coming, perceive your going; they

[1] De Lausanne, "Des Principes, etc., du Magn. Anim." (2 vols. Vol. i. is by Bruno), pp. 123–128. Paris, 1819. As the house around which the walk was made lay *west* from Bruno's house, the return walk was, of course, from west to east, and the girl's head must have moved in the same direction. The whole narrative leaves much to be desired in respect of clearness and precision. The exceeding awkwardness of the style is reflected in the English version.—*Translator.*

[2] "De l'Art d'Appliquer le Magnétisme Animal à la Thérapeutique" (*Le Propagateur*, p. 277. 1827).

fall asleep to awake, and then to sleep again, all at your will." Here are the experiments Dupotet had in mind when he wrote that passage:

"*Experiments at the Hôtel Dieu* (Nov. 1, 1820).—We were all assembled in the hall used for our seances, the patient alone excepted. Mr. Husson, physician of this hospital, said to me: 'Will you endorm the patient, and that very speedily, without touching her? I wish you would try to obtain sleep without her seeing you or being apprised of your coming hither.' I answered that I would try, but that I could not guarantee the success of this experiment, because action at a distance, through intervening bodies, depends on the special susceptibility of the individual. We agreed upon a signal that I should be able to hear. Mr. Husson, who, at the moment, held in his hand a pair of scissors, chose the throwing of them upon the table as the signal. It was proposed that I should enter a closet separated by a thick partition from the apartment we were in, and the door of which was secured by a strong lock. I did not hesitate to shut myself up in that closet, being unwilling to elude any difficulty, to leave any doubt in the minds of honest men, or to afford any occasion for malevolent criticism. The patient was brought in and was placed with her back turned toward the place where I was concealed and some three or four feet distant. The persons present wondered, with the patient, that I had not yet come, and from my delay concluded that perhaps I was not coming; it was wrong for me to keep people waiting—in short, the make-believe that I had failed to come was acted very plausibly. At the appointed signal, though I knew not where nor at what distance Miss Samson was placed, I began magnetizing, keeping the strictest silence and avoiding the slightest movement that might give her notice of my presence. It was then 35 minutes past 9 o'clock. Three minutes later she was asleep, and from the moment that I began to direct my will-action the patient was seen to rub her eyes and to show signs of drowsiness, and at last fell into her ordinary somnambulism. I repeated this experiment November 7, in presence of Professor Récamier. He took all possible precautions, and the result was, in all respects, the same as in our first attempt. The particulars of this second experiment are as follows: Upon my arrival, at 9.15, at the place of our seances, Mr. Husson came to tell me that Mr. Récamier wished to be present to see me endorm the patient through the partition. I promptly consented to the immediate admission of so respectable a witness. Mr. Récamier entered and talked with me, in particular about his belief as to magnetic phenomena. We agreed upon a signal; I went into the closet and was locked in. Then Miss Samson was brought, and Mr. Récamier placed her more than six feet from the closet—I not knowing where she sat—with her back turned toward it. He conversed with her and found her better. They told her I was not coming, and she wanted absolutely to withdraw. The moment that Mr. Récamier asked her *whether she digested meat* (these words were the signal agreed upon by Mr. Récamier and me), I began magnetizing her. It was then 9.32; three minutes later Mr. Récamier touched her, raised her eyelids, shook her by the hands, questioned her, and so we obtained proof that she was fully endormed. But these two facts did not suffice to demonstrate so strange a phenomenon."

In fact, this second experiment was very ill-contrived. The same hour was selected—9.35, 9.32—the same place, the same subterfuge to hoodwink the patient. All this was anything but ingenious, and this second experience, *qua* second (p. 35, *supra*) was positively of no value whatever. Bertrand had good right to retain his doubts. As for Récarmier, when Mr. Dupotet asked him, "Well, are you convinced now?" "Convinced? No," he replied, "but staggered."

"So we resolved to multiply the experiments, varying them, changing the hour and the wonted circumstances. What we did was this: I went one evening, accompanied by Mr. Husson and other physicians, to the ward where the patient was. [A new imprudence!] They placed me at the distance of several beds away from the patient, observing the strictest silence, so that my coming might not be noticed. At 7.08 o'clock I magnetized the patient; at 7.12 we all approached her, and were convinced that the sleep and the insensibility that habitually characterized her existed in the highest degree. I need not say that the day for the experiment was chosen by the physician-in-chief, not by me; that the observers had made sure in advance that the patient was not sleeping [it was upon this point that Bertrand's objections mainly bore: he declared that Mr. Husson, by his simple presence, might suggest the thought of an experiment]; and, finally, that my action was directed from a distance of about 20 feet. To put an end to all uncertainty as to the result of this wonderful (*prodigieuse*) action, this is what we did, or rather what I was ordered to do: Mr. Bertrand, doctor of medicine of the Paris Faculty, had witnessed the seances. He said that to him it did not appear strange that the magnetized patient should fall asleep, the magnetizer being placed in the closet; he believed that the concurrence of the same environing circumstances would, without my presence, bring about a like result; that, in fact, the patient might be naturally predisposed. He therefore proposed the experiment I am about to describe:

"The patient was to be made to come to the same place, to sit in the same chair at the same spot, and the same sort of conversation was to be carried on with her and around her; it seemed certain to him that sleep must follow. Consequently, I agreed not to come till a quarter of an hour after the usual time. At 9.45 began, in presence of Miss Samson, the pre-arranged proceedings. She was seated in the same armchair she usually occupied, and in the same position. She was asked various questions, then she was left in quiet. A pretense was made of giving signals, as on former occasions, by dropping the scissors and the like; in short, the customary practices were repeated exactly. But in vain did the observers look for the magnetic state to make its appearance in the patient. She complained of her side, was restless, rubbed her side, changed her place, and gave no sign of a need for sleep, whether natural or magnetic. The delay of a quarter of an hour being at an end, I repaired to the Hôtel Dieu, entering at 10.05. The patient said she had no inclination to sleep, nodded, and in one minute and a half was asleep, but did not respond till half-an-hour later."[1]

Such is the story told by the party most interested in the affair.

[1] Dupotet, "Traité Complet du Magn. Anim.," 4th ed., p. 182. Paris, 1879.

Let us now see what is said of it by the unbelieving *intransigentes*, Messrs. Burdin and Dubois:[1]

"In the first place, Mr. Husson visited the ward unexpectedly at 7 o'clock in the evening, an occurrence quite unwonted and out of keeping with the habits of so precise, so punctual a chief of service. Mr. Husson did not hide, but went straight to Miss Samson's bed, and to put her on the wrong scent [as though it were an easy thing to do with a somnambule], he addressed her next neighbor, saying to her: 'It is on your account I come this evening; I was anxious about you this morning, but I find you are better; be not alarmed and all will be well.' It was the somnambule that should have said, 'All will be well,' for now she is *fore-advised.* Nor is that all. Very adroitly the magnetizer is placed at the distance of one bed from his subject; a lamp, says Bertrand, lighted the ward, and stood behind the said magnetizer, so that he might make a Chinese shadow-picture of himself; and Mr. Husson, also at a short distance from the subject, had his eyes fixed on her. Now, was not that a neatly contrived experiment? . . . So then, what happened? Why this, that Mademoiselle, once the preliminaries were settled, exclaimed aloud for the edification of the experimenters: 'It is astonishing what trouble I have with my eyes; I can't keep awake.' And lo! she is asleep!"

But Messrs. Burdin and Dubois were not present at the experiment. Let us see, then, what is said of it by Bertrand, to whom the academic authors refer:

"Mr. Husson [says Dr. Bertrand] was so good as to consider my objections and to agree to an experiment which would serve as a counter-proof by showing to what extent the accessory circumstances I have just pointed out might act in the absence of the experimenter. It was proposed to have the patient come at the usual hour to the same room; she was to sit in the same chair; a show of giving a signal was to be made; in short, in the absence of the magnetizer, we were to act precisely as we had been in the habit of acting when he was present. All this was done as I requested, and *contrary to my anticipations the patient was not endormed.* As this experiment had not the result I had expected, I proposed a second one that seemed more conclusive still. This consisted in directing the magnetic action upon the patient not only unbeknown to her, but also at an hour when she would not be likely to suspect that any one was trying to magnetize her; this might be done by entering her chamber at night when all were in bed, and, after making sure that she was not asleep, then magnetizing her from a distance unbeknown to her. . . . Not till we had all retired to a corner of the ward at a certain distance was the place of the experiment chosen. Several circumstances conspired to render this experiment more than doubtful to me. A lamp that lighted the ward stood back of the magnetizer and at a small distance from him, so that his body, even though he did not stand erect, *might* easily perhaps have been seen by the patient. Another cause of uncertainty resulted from the very exactitude with which it was attempted to perform the experiment, for Mr. Husson, wishing to make sure that the patient was not asleep, was obliged to let himself be seen by her; and do what he might to lead her to believe that she

[1] "Histoire Académique," p. 260.

herself was not the object of his night-call, she must at least have had some doubts, enough to awaken her attention—all the more because for a fortnight she had been day after day the subject of a multitude of experiments, very many of which, as we have seen, were tried for the purpose of exerting some action or other upon her unawares."

Bertrand concludes his analysis by declaring that he did not contest the facts, but that when he signed the report he was far from confirming, thereby, the reality of the magnetic agent and from offering these experiments as conclusive.[1]

I am positively of the same opinion. They are not conclusive, but neither are they altogether valueless, as Messrs. Burdin and Dubois would have us believe. They were the first public experiments of the kind, and to Dupotet belongs the credit of having ventured to make the first step.

"Shortly afterward [says Bertrand] similar experiments were made at the Salpêtrière by men versed in the study of medicine and by distinguished students who have become physicians of repute. The result was to convert to a belief in the phenomena of somnambulism the author of the "Physiologie du Système Nerveux," Dr. Georget, who in 1821 recorded in that very work the result of his researches. These experiments commanded also the belief of Dr. Rostan, author of several excellent works, and of a great number of articles in the new "Dictionnaire de Médicine," a compilation in which he has just published an article on "Animal Magnetism," wherein he sets forth the observations that wrought conviction in him. Mr. Georget, as well as Mr. Rostan, declares the existence of a special agent, and in particular believes in the influence of the will of the magnetizer, to which he assigns a rôle as important as that assigned to it by Messrs. Deleuze and Puységur. But that is not much to be wondered at, so easy is it to be illuded, when one observes creatures for whom the most baseless belief becomes the source of real phenomena. I have passed through the illusion under which the distinguished men I have named still remain. May I be permitted to hope that they one day will adopt the point of view at which I stand? For the rest, the important thing is, the testimony they have given as to the reality of the phenomena; it came at an opportune season to strengthen the testimony already given by men whom no one can reasonably suspect of an intention to deceive, and it will no doubt help to win the belief of the scientific world.

"Other experiments were made at the Pitié, at the Charité, under the direction of Mr. Fouquier, at the Hospital of St. Louis, and everywhere results more or less noteworthy were obtained; but officialdom, which ought not to have remained a stranger to researches conducted under the direction of enlightened physicians and that could not have any untoward effect on the patients, opposed them blindly, and hindered them in every way."[2]

Bertrand was mistaken as to the definitive outcome of the experiments made at a distance. Five years after the publication of his

[1] Bertrand, "Du Magnétisme," pp. 259-265. Paris, 1826. [2] *Id.*, p. 266.

book, new proofs were brought forward by the academic commission that was appointed about the time when the work appeared. Dr. Foissac repeated Dupotet's experiments with entire success and under the best conditions.[1] Morin, another unbeliever, in reporting these facts, is able to raise but one objection, viz.: that there might have been collusion between Dr. Foissac and the patient. It is difficult to accept the supposition of Mr. Morin, or rather of Messrs. Burdin and Dubois. And, in fact, those gentlemen did not make it seriously; but they are in the right when they say that in handling this sort of question all delicacy must be laid aside, and that Mr. Foissac ought not to have known beforehand the precise time.

9. "Sleep at a distance [says Lafontaine] is not produced save upon persons that have been magnetized repeatedly. At Renner, Mr. Dufihol, rector of the academy, and Mr. Rabusseau, inspector, came one day with several physicians to the hotel where I lodged. After we had conversed for a good while, Mr. Dufihol asked me to accompany him home, saying that a lady wished to talk with me. I took my hat and went with Mr. Dufihol. After crossing the court yard we entered one of the parlors of the hotel, and Mr. Dufihol began a conversation, the purpose of which I did not see. After a quarter of an hour he said to me: 'You have maintained that you are able to endorm your subject at a distance without his being fore-advised; will you now try that experiment?' I agreed. 'How much time will it take?' 'Four or five minutes.' 'Begin.' Three minutes after I told Mr. Dufihol that the subject must be asleep. He requested me to remain in the parlor, crossed the court-yard himself, went upstairs, and as he neared the door, he heard the other gentlemen say to the subject: 'Well, you are sleeping? Awake! He is asleep!' Mr. Dufihol entered hastily and found the subject endormed; then he called me, and said: 'In the face of facts like these, gentlemen, we must believe; it was I that asked Mr. Lafontaine to endorm the subject from the large parlor of the hotel."

That experiment was well contrived. Here are two more, arranged *ex improviso* likewise:

"The seance ended, many persons surrounded Mr. Lafontaine and discussed with the liveliest interest the different effects of magnetism. Just then took place the most conclusive experiment of the evening. The subject had withdrawn, and was talking with some *gardes de ville* at one of the braziers in which fire had been made to warm the hall. 'Could you endorm him from here?' some one asked Mr. Lafontaine. 'Undoubtedly,' was his reply; 'stand around me, so that he may not see me.' After a few moments the subject was sound asleep. . . .

"At Cinq-Mars-la-Pile, two hours before giving a public seance, I happened to be at the house of Dr. Renaud. A dozen persons were present; the talk was about magnetism, and it was proposed that I should, from the doctor's house, endorm my subject at the hall of the Mairie, where I was to give the seance. I agreed. The conditions were that I should not leave the house; that two of the gentlemen in the company should remain with me and should tell me the moment

[1] "L'Art de Magnétiser," 5th ed., corrected, p. 92.

when I was to commence; that two others were to go and find the somnambule, who was at the hotel, and conduct her to the Mairie, telling her nothing about what was to be done. From the doctor's residence to the Mairie was about half a kilometer. The hour having come, and the two persons that had remained with me—one of whom was Mr. de la Bérandière—having told me that I might begin, I thought, four minutes later, I could assure them that the subject was asleep. We then set out for the Mairie, and when we arrived there the subject was sleeping. Not till five minutes [after the operation began] had the sleep been perfect. In the second minute the first effects had been noticed, such as winking and drowsiness."

We may add that Lafontaine did not believe in direct will-action or will-transmission, but only in the emission of a fluid, under the control of the will.

10. Dr. Dusart completes as follows his observation on Miss J.: "Each day [he says] before leaving I gave the order to sleep till a fixed hour of the next day. One day I came away, forgetting that precaution, and had gone 700 meters away when I adverted to it. I therefore formulated the order *to sleep till eight o'clock the next day*, and went my way. On the morrow I arrived at half-past seven o'clock. The patient was asleep. 'How comes it,' I asked, 'that you are still sleeping?' 'Sir, I am obeying you.' 'You are mistaken; I left without giving you any order.' True, but five minutes afterward I *distinctly heard* you tell me to sleep till eight. Now, it is not yet eight.'

"The latter hour was the one I usually set for her to awake. Possibly habit produced an illusion, and there may have been simply a coincidence. In order to satisfy my mind as to that and to leave no room for doubt, I commanded the patient to sleep till she should receive the order to awake.

"In the course of the day, having found a moment of free time, I resolved to complete the experiment. I left my home (seven kilometers distant), giving at the same time the order to awake. I reached the house of the patient and found her awake. Her relatives had, at my request, noted the precise moment of her awaking; it was exactly the moment at which I had given the order. This experiment, repeated many times, at different hours, always had the same result."

It is really an interesting one. First, because it seems to prove that, not only is forehead-contact not necessary, but that the action can be exercised at the distance of seven kilometers; and then because it proves that, under these conditions, the influence may have a bearing not only on the fact of sleeping, but on that of awaking also, probably with specialization of a particular thought—that of a stated hour.

But here is something that will seem more extraordinary still:

"January 1, I suspended my visits and ceased to have any relations with the family. I had heard nothing more about them when, on the 12th day of the month, while I was going my round in the opposite direction and ten kilometers distant from the patient, I asked myself whether, in spite of the distance, the suspension of all relations, and the intervention of a third person (for the patient's father magnetized

her then) it would be still possible for me to make her obey me. *I forbade the patient to allow herself to be endormed;* then, half an hour afterward, reflecting that if, by an extraordinary chance I should be obeyed, that might prove injurious to the afflicted girl, I lifted the prohibition and thought no more about it. I was much surprised when, the next day, at six o'clock in the morning, a messenger came express to my house bearing a letter from Miss J.'s father. He wrote that the day before, at 10 o'clock A. M., he had succeeded in endorming his daughter only after a prolonged and very painful struggle. The patient, once endormed, had declared that if she had made resistance it had been by my order, and that she had not fallen asleep till I permitted. These declarations were made in the presence of witnesses, whom the girl's father got to sign the notes of them made at the moment. This letter I have preserved; its contents were confirmed to me later by Mr. ——, who added some circumstantial details."

Thus it becomes probable that with an exact knowledge of the conditions of the phenomenon we may be able to communicate our thoughts at a distance, as we now converse by telephone.

Dr. Glay adds to this observation a remark having a bearing on experiment. "It seems," he says, "that Dr. Dusart succeeded in endorming his patient at a distance only after subjecting her to an education process. Thus, he says that at first he endormed her very many times by mental order, but that the order was given from very near. *Evidently we have no very clear understanding as to what may be the influence* of such education; it may be, nevertheless, that here is a condition favorable to the development of these phenomena, should they be proved real."

We can, I believe, get a pretty fair notion of the influence of this education:

a. In the first place, such influence need not cause us any surprise, for it is observed in all hypnotic and magnetic phenomena, without exception: the subject's sensibility grows in proportion to the experimentation. The hypnoscope enables us to determine this fact; and, as I observed in a note[1] communicated to the Société de Biologie in 1884, there exists with respect to this point a very sharp contrast between imaginary and real sensibility. Persons who think themselves highly sensitive, very "nervous," who have faith in magnetism, but who do not possess this special *sensibility*, which does not depend at all on the will or on faith, experience various sensations, more or less strong, at the moment of a first hypnoscopic test. These sensations are produced by fear, by expectant attention—in a word, by the imagination. Make the test a second time, and you will see these sensations rapidly grow less and disappear, whereas the effects due to real sensibility persist and grow more pronounced with each application.

If, after a first hypnoscopic test, you hypnotize or magnetize the subject, say for a month, and then apply the test again, you will

[1] See Appendix I.

always find evidence of greater sensibility. Why? Because the action, consisting of a reflex influence between the brain and the ganglia, must needs present the phenomena proper to reflex action in general, which is a thing that is learned, that strikes root, and that becomes more and more easy. Any nerve-route whatever, traversed once by any excitation, no matter what, will present less resistance at the second passage of the same excitation. Herein consists the difference between a wire and a nerve-fiber, particularly when the fiber is connected with living cells. This is what Ribot has called *organic memory*,[1] and this memory must be no less favorable to slight excitations than to the ordinary mechanic actions.

b. We must not forget that though hypnotic sensibility is independent of the subject's conscious will, it is not so with his unconscious. The unconscious may be regarded almost as a privy government, often, if not always, more powerful than that which under the style of Ego I. reigns in the light of publicity, but—governs not. With this Ego I., more pompous than puissant, you may treat of matters of a superficial sort, but with Ego II. you can conclude treaties with regard to all vital functions.

To it you may, for example, say: "While Ego I. is sleeping you will watch, reckoning the hours and minutes, and you will wake him at such an hour; you are to have an eye upon your first minister, who is called 'Exchange of Matter,' so that he shall not hurry his work; you will carry on and equalize the life-movement in all the provinces of your realm, guard the frontier against invasion, expel foci of disease that break your rest," etc., and he will obey you; he has the power to obey you. Consequently the will of Ego II. can go out to meet us, can aid us, can facilitate more and more our task.

c. There must be a strong analogy between a spoken voice and a mental voice.[2] Now, we sometimes have difficulty in understanding what is said by one who is a stranger to us; he speaks too rapidly, or in too low a voice, or with faulty pronunciation; but little by little we grow used to this; associations are formed, and, as a mother understands the babble of her child, we learn to associate the more or less jumbled sounds with definite ideas. Probably the vibrations that transmit thought and will are no less confused, no less imperfect; consequently we must have them repeated to us over and over, in order that we may perceive their differences; and it is easy to see how habit, training and exercise help us to perceive them.

d. Finally, as we have already observed, the action upon the subject of a center of radiation from without,[3] and an adjustment in conformity with the dynamic nature of that center, are effected little by

[1] Ribot, "Diseases of Memory." (HUMBOLDT LIBRARY No. 46.)

[2] *Une voix parlée, une voix mentale.*

[3] *L'envahissement du sujet par un foyer rayonnant extérieur.*

little, and constitute what is called "rapport." And this rapport is a necessary condition of all mental transmission.

11. "One day [says Mr. Richet], being at breakfast with my colleagues, among them our confrere Mr. Ladouzy, then, like myself, an *interne* of the Beaujon Hospital, I affirmed that I could endorm a patient at a distance, and that I would simply, by an act of my will, make her come to where we were. But after waiting ten minutes, no one having come, the experiment was considered to be a failure. In fact, it was not a failure, for after a while word was brought to me that the patient was walking up and down the corridors endormed, trying to have a talk with me, and not finding me. So in fact it was, and I could get from her no explanation of her sleep and of her wandering about but this, that she wanted to talk with me."

Here we see a lack of magnetic training. Had this patient been accustomed to the experiments, like the somnambules of Dupotet and Foissac, or even like Mr. Gibert's subject, Mrs. B., she would doubtless have known the reason of her promenade. Another point is worthy of mention: the somnambule did not *find* Mr. Richet, and that for sundry reasons. First, because Mr. Richet had ceased to influence her; then, because where physical attraction does not combine with the mental action (as in Bruno's experiment), the subject cannot find his way; he knows he must go somewhere, but whither he knows not; finally, it is probable that this dominant thought of going to see Mr. Richet developed in her a *somnambulic monomania*, which, like all monomanias, hinders clear vision. Often it happens that one will be searching for a knife, for instance, that lies before his eyes on the table; the more persistently he searches the blinder does he become to the object. At last he gives up looking for it, and then finds it. We may recall an occurrence of this sort in our third experiment at Havre, where Mrs. B. was looking for Mr. Gibert, but could not find him. Nevertheless, she had come from the distance of a kilometer in obedience to the mental order. This explains for us the unsuccess of many magnetizers, who, after having mentally attracted their subject, cannot make him come to them after they change their place. The subject grows impatient, stubborn, and has no sense for anything more.

"Another time [writes the same author] I repeated this experiment, varying it in the following way: I asked two of my colleagues to visit the ward under pretense of examining some patient or other, but really in order to observe how No. 11 would act, it being my intention to endorm her at that moment. A little afterward they came and told me that the experiment had failed. But this time also it was successful, for they had mistaken for No. 11 the patient in the next bed to hers, who, of course, had remained awake, while No. 11 had been put in a sound sleep.

"I ought [he adds] to have repeated this interesting experiment, to have varied it, and to have made the conditions more precise; but in

matters of this sort one cannot do all that he fain would do, and only those who have experimented know what difficulties of all kinds, moral and otherwise, beset the path of methodical experimentation. After a few weeks the patient went back to her own district, to Béziers, I believe, and I have not heard of her since. Since that time (1873) I have not been able in one single case to produce this phenomenon of somnambulism at a distance. If, then, the phenomenon exists—and it were not easy, I think, absolutely to deny it—it is extremely rare, and occurs only under special circumstances that hitherto have escaped scientific verification."

We shall endeavor to define these special circumstances with the aid of recent research. But first let us continue our record of experiments.

12. Mr. Héricourt completes his note, already cited, as follows:

"Soon my thoughts were no longer about exerting my action from one end of a room to another; the same results were obtained in acting from one part of a house to another, and from one house to another house in a more or less distant street. The circumstances amid which I thus exerted, for the first time, this long-distance action, are worth stating in some detail. Being one day in my study (I lived then in Perpignan), the thought occurred to me to endorm Mrs. D., who, I had every reason to believe, was at home, and who lived in a street some 300 meters distant from mine. By the way, I was far from believing that the experiment would succeed. It was 3 o'clock, P. M., and I kept walking to and fro, thinking very intently of the result I wished to produce; and I was fully occupied with this exercise when I was called to see some patients. As the cases were urgent, I, for the moment, forgot Mrs. D., whom I was to meet toward half-past four on a public promenade. Having repaired thither at that hour, I was much surprised not to see her there, but thought that, after all, my experiment might have been successful; so about 5 o'clock, lest anything should be amiss, and to restore things to their normal state, in case that state had been, in fact, disturbed, I bethought me, to ease my conscience, to awaken my subject with the same strong effort with which I had shortly before sought to endorm her. I happened to see Mrs. D. that evening, and this is what she told me, purely of her own accord, and without any allusion whatever, on my part, to her absence from the promenade. Toward 3 o'clock, being in her bedchamber, she was suddenly possessed by an irresistible desire to sleep; her eyelids were leaden, her legs refused to support her—she never had been in the habit of sleeping in the daytime—so that she was hardly able to go to her drawing-room and there throw herself upon a sofa. Her maid having come in to speak to her, found her mistress, as she afterward told her, pale, motionless, her skin cold, *corpse-like*, to use her own expression. Justly alarmed, the servant began to shake her vigorously, but with no success beyond making her open her eyes. At that moment Mrs. D. was conscious, as she told me, only of a violent headache, but that, it seems, disappeared suddenly toward 5 o'clock. That was just the moment when I thought of awakening her.

"This narrative, I repeat, having been spontaneous, no further doubt remained; my experiment had surely been successful. In

order to repeat it under conditions as stringent as might be, I did not acquaint Mrs. D. with what I had done, and I set on foot a whole series of experiments, bringing as witnesses a number of persons who consented to fix the conditions and to verify the results. Among these witnesses I may mention the surgeon-major and a captain in the battalion of chasseurs in which I was aide-major. All these experiments are ultimately reducible to the following type: Being in a drawing-room with Mrs. D., I told her I would try to endorm her from a neighboring apartment, the doors being closed. I then proceeded to that apartment and there remained a few minutes, my thought being distinctly to let her remain in the waking state. When I went back to the drawing-room I, in fact, found Mrs. D. in her normal state, and making merry over my want of success. A moment afterward, or on another day, I would enter the same neighboring apartment on one pretext or another, but now with the set purpose of producing sleep, and almost within a minute the most complete result would be obtained. Here no other suggestion than the mental one is to be thought of, for *expectant attention* when brought to bear with full force in the preceding experiment, had been absolutely without effect. The conditions of these experiments controlling[1] one another as they do, are so simple and so effective, that I call attention to them as constituting a sort of schematism for use in demonstration."

This observation is highly instructive. In fact, negative control-experiments are of special interest. We recall a counter-proof of this kind demanded by Bertrand, and which was successfully made by Dupotet. Similar facts are found in Mr. Peter Janet's narrative, and in most of the cases wherein an action purely mental is alleged. The subject may be touched, passes may be made, we may pretend that it is our purpose to endorm him, and no result will follow.

But this is of very rare occurrence; the majority of very highly sensitive subjects undergo ideoplastic action, and I even believe that some of those who are capable of being influenced at a distance will not withstand an imaginary action; and that consequently Mr. Héricourt's negative test cannot be decisive. But what appears to be certain is, that subjects that are suggestionable mentally, or from a distance, are less suggestionable verbally. They feel the real action, however weak it may be, but do not influence themselves. True, this may be due to training rather than to any positive difference in sensibility. In these latter times suggestion is the fashion; practitioners are suggesting all sorts of hallucinations to their subjects; and the Nancy school has for a long time been doing nothing else. Such being the case, it is no wonder that there should be plenty of subjects to afford rich amusement, though they be quite unsuited for a serious study. Where all is imagination, true action remains unperceived. Quite different was the practice of sober-minded magnetizers like

[1] The word is used in its original, etymological sense of "checking by a double register or double account." Webster marks "control," in this sense, *obsolete*. But *multa renascentur quæ iam cecidere!—Translator.*

Bruno, Puységur, Deleuze, etc. They took pains to lead their somnambules without driving them, and to develop their simple faculties rather than their suggestional mobility. Verbal suggestion is not to be disregarded, for it may render great service to therapeutic; but we must, above all, develop the native properties (*propriétés sincères*) of this extraordinary sensibility if we would make real progress as regards theory. Little wonder that with suggestion run mad, magnetism has been made a laughing-stock and somnambules have been replaced by hurdy-gurdies.

13. Let us again consider the experiments made from a distance upon Mrs. B.

a. "Without advising her of what he intended to do, Mr. Gibert shut himself up in a neighboring room, at the distance of 18 or 20 feet, and there tried mentally to give her the order to sleep. I remained with the subject [says Mr. Janet] and observed that, after a few moments, the eyes closed and sleep began. But what seemed to me specially curious was, that in the lethargy she was not at all under my influence. I was unable to produce in her either contracture or attraction, though I remained beside her while she was entering the sleep. On the other hand, she was entirely obedient to Mr. Gibert, though he had not been present; finally, it was Mr. Gibert that had to awaken her, and that proves that he had endormed her. There may be some doubt, however, as to this point. Mrs. B. certainly was not unaware of the presence of Mr. Gibert in the house; so, too, she knew he had come to endorm her; hence, though the supposition seems to me to be hardly probable, one might say that she put herself to sleep by suggestion at the very instant when Mr. Gibert was giving the order from the neighboring room.

b. "October 3, 1885, I called on Mr. Gibert, at his residence, at half-past eleven o'clock in the forenoon, and asked him to endorm Mrs. B. by a mental order without quitting his study. The woman was, on this occasion, in nowise forewarned, for we had never endormed her at that hour. She was in another house at least 500 yards distant. I forthwith repaired to where she was, to note the result of this singular command. As I expected, she was not at all asleep. I then endormed her myself by touching her, and when she was in somnambulism, before I had addressed any question to her, she began to talk as follows: 'I know Mr. Gibert wanted to endorm me . . . but as soon as I noticed that, I went and got some water and *dipped my hands in the cool water*. . . . I do not wish to be endormed in that way. . . . I might become talkative . . . that puts me out and makes me ridiculous.' It turned out that she had, in fact, dipped her hands in cold water before my arrival. I record this experiment though it failed, because it seems to me interesting from many points of view. Mrs. B., then, appears to be conscious, even in the waking state, of the influence that controls her; she is able to withstand the sleep by dipping her hands in cold water; finally, she did not lend herself kindly to the experimentation, and that fact may be regarded as a guarantee of her honesty.

c. "October 9, I again visited Mr. Gibert and asked him to endorm Mrs. B., not immediately, but at twenty minutes before 12. I went

straight to her unaccompanied by Mr. Gibert, who I am certain could not have had any communication with her; I expected to be able to prevent her from putting her hands in cold water should she attempt to do so again. I was unable to watch her as I had intended, for she had gone to her chamber a quarter of an hour before and closed the door, and I thought it best not to put her on her guard by having her called down-stairs. At fifteen minutes before 12 I went up to her room with some other persons who accompanied me. Mrs. B. was reclining in a chair in a very uncomfortable posture and in deep sleep. It was not natural sleep, for she was totally insensible and it was absolutely impossible to awaken her. I remark again that neither I nor any one of those present had any influence upon her or was able to produce any contracture whatever. The first words she uttered as soon as the somnambulism appeared spontaneously were these: 'Why send them so? I don't want you to make me act foolishly. Do I look like a fool? Why does he, Mr. Gibert, endorm me from his house? I didn't have time to dip my hand in my basin.' As I had no influence over her, it was impossible for me to awaken her, and as we could not leave her so we had to go and fetch Mr. Gibert. As soon as he came he produced all the phenomena which on that day I was not able to produce, and at last awakened her with the greatest ease. Is it to be supposed that my presence in the house and the knowledge I had of the time set by myself for the sleep to come on, had any influence upon her and put her to sleep? I think not, but still the supposition is not unreasonable. We resolved to make the experiment in a different way.

d. "October 14, Mr. Gibert promised me that he would endorm Mrs. B. at some hour of the day to be set by him or by a third person, but which I was not to know. I came to the pavilion where Mrs. B. was about half-past 4 o'clock. She had already been asleep for fifteen minutes, and consequently I had nothing to do with that sleep, and all I did was to ascertain its existence. I observed the same insensibility, the same characters as before, save that the lethargy seemed still more profound, for there was no state of somnambulism at all. Still, there were produced on that day other phenomena, but these belong to another order of ideas of which I will speak presently. Mr. Gibert did not come till half-past 5. He then told me that at the suggestion of Mr. B., he had given thought to the endorming of the subject about fifteen minutes after 4 o'clock, and that he was then at Graville, that is to say, at least two kilometers distant from her. He had no difficulty in producing contracture or in awakening the subject. It were well could this experiment have been repeated many times, and it is to be regretted that the departure of Mrs. B. prevented us from making it again. Nevertheless to me it seems decisive, considering that it is but the complement of prior experiments and that it is connected with other facts of the same kind that we must now set forth.

e. "October 14, the same day that Mrs. B. was endormed from Graville, I observed during her sleep the following phenomena: At five o'clock precisely Mrs. B., while asleep, began to moan and to tremble, and then to mutter these words: 'Enough, enough, it is very unkind of you.' She sat up, and, moaning, rose to her feet and made a few steps; then laughing aloud, she threw herself backward into the armchair and fell into deep sleep. At five minutes past five the same

scene precisely was enacted: she rose, stood up, and seemed inclined to walk; after a few moments she said, laughing: 'You cannot. Let your thought wander ever so little, and I am myself again;' and, in fact, she lay down again and once more was asleep. The same scene was repeated at ten minutes past five. When Mr. Gibert arrived, at half-past five, he showed me a card that had been sent to him by a third person, Mr. D.; he could not have had any communication whatever with Mrs. B. from the time when the card had been sent. It was suggested that Mr. Gibert should order Mrs. B. to perform different acts of some complexity at intervals of five minutes, after five o'clock. These acts, plainly because they were too complex, were not performed; but at the very moment when Mr. Gibert, at Graville, was ordering them to be done, I, at the distance of two kilometers, with my own eyes, saw the effect those orders produced and a beginning made toward carrying them out. Mrs. B., in fact, seemed to have cognizance of the orders, to withstand them, and to be able to disobey them only because of a sort of distraction on the part of Mr. Gibert. We began this experiment again, placing ourselves this time beside her during the lethargic sleep. Strange to say, the result, contrary to what might have been expected, was not more noteworthy. The person who endorms Mrs. B. can easily enough, by a mental order, make her sit up, and even rise to her feet; but whether because the concentration of thought does not last long enough, or whatever the cause may be, Mrs. B. is not slow to 'get herself back again,' as she says, and to resume the reclining posture. The order mentally given has an influence that seems immediate, but, as far as we have been able to see, that influence seems not to be greater anear than from afar."[1]

"Later, in a new series of experiments, after a rather lengthy training of the subject, I myself succeeded in producing at will this curious phenomenon. Eight times consecutively I essayed to endorm Mrs. B. from my own house, taking every possible precaution so that nobody might be aware of what I intended to do, and each time changing the hour of the experiment, and in every instance Mrs. B. was put in the hypnotic sleep [hypnotism from a distance!] a few minutes after the time of my beginning to fix my thought upon the matter."[2]

The details of these new experiments will be read with interest. I take them from Mr. Janet's second note presented to the Society for Physiological Psychology, May 31, 1886:

"These new researches have had to do particularly with sleep produced by action at a distance, for that phenomenon is of the highest importance and seems to be easily verifiable. As I was resolved to make sure of the reality of the phenomenon, I sought to produce it myself repeatedly and with all possible precision, and will begin with an account of these experiments.

"Mrs. B. had been back in Havre since February 10; her health had continued to be very good, and she had had no nervous attack since her last journey. Once only had she been indisposed, she said, and the circumstances of her indisposition were these: A person living in

[1] *Bull. de la Soc. de Phys. Psych.*, 1885, vol. i. Paris, 1886.

[2] P. Janet, "Les Phases Intermédiaires de l'Hypnotisme." *Rev. Scientif.*, May 8, 1886.

the part of the country where she was, and who at other times used to endorm her with the greatest ease, had tried again to produce in her the magnetic sleep. He made the attempt repeatedly during three consecutive hours, yet did not succeed in endorming her. As a consequence of this experiment Mrs. B. had a severe headache, and was indisposed for some days. She did not understand the matter at all; in her simplicity she believed that she could not be endormed any more, and that even we could no longer succeed. But we were not at all concerned, for we remembered how, on the eve of her leaving Havre, at the last somnambulic seance on October 14, Mr. Gibert had forbidden her to be endormed by anybody outside of Havre. The suggestion had been made mentally, that is to say, Mr. Gibert had done nothing but simply to think upon that command while nearing his forehead to the forehead of Mrs. B. Still, I cannot cite this fact as a clear case of mental suggestion, for I am not sure that we did not discuss in her presence, during the sleep, the possibility of such suggestion. In any case, it is seen that the suggestion was perfectly effective during four months. As soon as Mrs. B. was with us again, Mr. Gibert, without a word of explanation, pressed her hand as he had been wont to do before, and in two minutes she was asleep; the following day I endormed her with the greatest ease in a few minutes.

"I tried by endorming her often myself to acquire over this woman an influence sufficiently strong to warrant me in essaying with some prospect of success to give her from a distance the order to sleep. At first I would endorm her by holding her hand or seizing her thumb, without trying any other procedures. After a few days I was able to bring about sleep much more speedily. Previously it took me three or four minutes, and sometimes longer, to endorm Mrs. B. I produced the sleep now in half a minute. To endorm Mrs. B. it was no longer necessary to fix the mind on the order to sleep; physical action exerted upon her hypnogenic point on the thumb superseded all other kinds of influence. The mental command retained its importance when the subject was not touched, when she was endormed by mental suggestion exercised in the room where she was. That experiment was still performed very readily, but there was no certainty that the attitude of the magnetizer did not play a greater part in producing the sleep than his mind did.

"After a dozen seances, at which I myself had endormed Mrs. B. six times, I essayed to give her the order to sleep, I not being beside her, but in a neighboring room. The experiment was successful. After thinking for five minutes upon endorming her, I entered her room and saw her completely endormed, her head and her body leaning in the direction of where I had been. The experiment, however, is not conclusive, for Mrs. B. evidently suspected my intention.

"February 22, after fourteen somnambulic seances, and after endorming her myself eight times, I for the first time attempted to give her from a distance the order to sleep. I was at my house, some 400 or 500 meters away from the pavilion where Mrs. B. was, when I essayed to concentrate my mind upon the order, 'Sleep,' as I had many a time done when she was present. I did not perhaps bring the necessary conviction, nor did I spend the necessary time, for I 'thought' hardly more than five minutes. At all events, I did not visit her till an hour later, being persuaded beforehand that my

attempt was a failure. To my great astonishment, the people of the house told me that Mrs. B. had been much indisposed for an hour; that she had had spells of drowsiness and been forced to suspend her work; that to free herself from this feeling she had had to drink a glass of water and to bathe her face and hands. Mrs. B. herself told me of her indisposition, which she did not explain. It is well to remark here that in the waking state she has not the slightest suspicion that she may be endormed from a distance. This coincidence—which, to say the least, is a singular one—showed two things: (1) That probably I exercised from a distance a certain action upon this woman, and that there was good reason for trying again; and (2) that, for whatever reason, whether for want of accustomance or because of the action of the cool water, Mrs. B. was able still to withstand that action and so was not endormed.

"For two days more I endormed her from anear by touching her. During her waking state I asked her not to put her hands in water again; without giving her any reason, I persuaded her to believe—what was not without truth—that she was doing herself great harm by struggling so against a transient drowsiness. In the state of somnambulism I repeated the prohibition, so reinforcing my recommendations with the power of suggestion; and February 25, without acquainting any one with my intention, I made the same experiment again. Under the same conditions as before, about five o'clock in the evening, I gave thought to endorming her, fixing my mind as intently as possible, and almost without distraction, upon that object for eight minutes; then I went straight to her. She lay upon a sofa in deepest sleep; no shaking could arouse her. But if I but pressed her fingers, or touched her lightly on the arm, the subjacent muscles underwent strong contracture; if I opened her eyes to the light she went into true catalepsy, with the characteristic immobility of attitudes; if I closed her eyes, she reverted to the prior state. Thus she was plainly in the hypnotic sleep, which, by a strange coincidence, had set in just a few minutes before my coming. She was not slow to bestir herself (*s'agiter*) and to talk in the lucid somnambulism; she showed great joy on finding me near her, and was perfectly aware that it was I that had endormed her at five o'clock.

"Two further experiments, one on February 26, and the other on March 1, were not entirely successful; Mrs. B. only felt an indisposition, and was distracted in her mind by persons who were talking to her at the moment when she was about to fall into the sleep.

"But March 2, at my house, I began at 3 o'clock P. M. to give the same order. I did not see Mrs. B. till an hour later and found her in a singular attitude. She was seated and was hemming a napkin; her eyes were open; the motion of sewing went on with great regularity but with extraordinary slowness—she took no more than three or four stitches a minute. Without speaking a word, I seized her arm and left it in the air; it stayed there motionless. She was in true catalepsy, and that state continued, to the amazement of the persons present, for one hour. Little by little she had ceased to answer questions, and had remained thus motionless. I lowered her eyelids, and forthwith she fell back, and in that state of somnambulism, in the lethargic form, kept repeating, 'Oh! I am sleepy. You make me ill by talking to me. I am sleepy; I am ready to drop. Mr. Janet does not wish . . . . when will he come?' In a

moment of lucidity she recognized me, took me by the hand, with an exclamation of satisfaction, and then fell into quiet, dreamless sleep.

"On the next day, March 3, Mrs. B. was not endormed and was very well.

"On the 4th a curious incident occurred. I wanted to endorm Mrs. B. from my house by means of the usual mental order, and had been giving thought to the act for three or four minutes, when several persons coming in interrupted my singular occupation. To begin again was impossible, and when, an hour later, I visited the pavilion where Mrs. B. was, I supposed the experiment had failed utterly. Mrs. B. was in a chair, apparently asleep since three-quarters of an hour before; in accordance with directions from me no one had disturbed her. I wished to take her hand to produce the characteristic contractures, but she at once started, opened her eyes, and rose to her feet, saying that she was not at all asleep. Nevertheless, her eyes were dull, her walk unsteady, and I had to support her in order to conduct her to another room. But she soon was sound asleep after touching my hand. Is there not something curious in this drowsiness, this half-sleep, coming just on the day and at the hour when my thought was fixed upon endorming her, though I had not sufficient time?

"March 5, under the same conditions, this time about 5 o'clock P. M., for ten minutes I gave thought to endorming her; a few minutes later I found her in the same cataleptic state already described.

"March 6, Mr. Gibert essayed to endorm her from his house at a quite different hour—8 P. M. He was entirely successful, though he had not endormed the subject for eight days. We may remark that on this day a third person had regulated his watch by Mr. Gibert's, and observed Mrs. B. closely. It was found that she fell asleep at three minutes past 8 exactly. Such precision makes chance coincidence highly improbable.

"For a few days following we made no attempt at producing sleep from a distance, and on March 9, when I tried to recommence the experiments, I failed.

"March 10, Mr. Gibert endormed her from his house. The same day he made a very interesting experiment. But as I was unable to be present when it was made, and as it was repeated later, I defer the description of it. On the 11th and 12th no experiment. On the 13th I endormed her from my house at 4 P. M.; at 4:15 I found her in the cataleptic state. She was sewing, with the same automatic movement as before; her task was a rather complicated one, and she performed it well, but very slowly. Without speaking a word, without touching her, I simply gave her the mental order to sleep on and more deeply. She gave a sigh, the movements of the hands ceased, and she remained motionless in the last position assumed. I persisted, and she leaned back in the state of complete muscular relaxation. A tap on the tendons of the wrist now produced the contractures special to lethargy.

"March 14, at 3 P. M., I again endormed her in the same way, and found her in the state of lethargic somnambulism, motionless.

"March 16, it was agreed between us that Mr. Gibert should endorm Mrs. B. by mental action from his house, and that he should endeavor, while still at home, to make her get up and come to us. My brother, Julius Janet, *interne* of the Paris hospitals, who happened

then to be in Havre, was to go with me to Mr. Gibert's before 8 P. M., at which hour it was our intention to begin the experiment. An unforeseen delay prevented us from going to Mr. Gibert's early enough, and the experiment could not begin till 9 o'clock. I note this insignificant incident, because if by any extraordinary chance Mrs. B. had been advised of our intention, she would have fallen asleep, perhaps, and have started out at 8 o'clock, and not at 9. Now see what did happen. As I did not wish to have the sleeping woman walk through the streets unattended, I left Mr. Gibert and went toward the pavilion where she was. I did not enter, lest my presence should produce a suggestion, but remained on the street at some distance. A few minutes past 9 o'clock Mrs. B. came briskly out of the house. She was bareheaded and walked at a rapid pace. I went up to her and saw that her eyes were fast shut, and that she manifested all the signs of her somnambulic state. She avoided all obstacles so deftly that I was reassured, but she was very slow to recognize me. At first she repulsed me—she did not wish, she said, to be accompanied. After going some 200 meters she knew who I was and seemed to be pleased that I was with her. But I was worried a good deal by her frequent halts. She would stop and sway to and fro as though about to fall. I was afraid lest she should suddenly fall into a state of lethargy or of catalepsy, which would have made the walk difficult. But nothing of the kind happened; she righted herself and reached the house without a mishap. Hardly had she entered when she dropped into an armchair in profoundest lethargy. This lethargy was interrupted only for an instant by a period of somnambulism, during which she murmured: 'I am come; I saw Mr. Janet. I considered that I must not come by way of Etretat Street—too many people there.' (She of her own accord took another street.) 'A man came up to me, said I was blind, the fool.' Then she remained for a good while asleep. Later she was somnambulic again and said that she had felt much fatigue and hesitation during the walk because, as she said, Mr. Gibert had not thought continuously enough upon making her come. She had been endormed, as I was informed afterward, a few minutes before 9 o'clock, that is to say, at the time when Mr. Gibert had been 'thinking,' but she had not set out for his house till five or six minutes later.

"This experiment was repeated with the same success, once in presence of Mr. Paul Janet on April 20, and another time in presence of Messrs. Myers, Marillier, and Ochorowicz, on the 22d. We may remark that Mrs. B. does not sleep so evenings, and does not walk in somnambulism.[1]

"Such is the history of the experiments upon the producing of sleep from a distance, made during this second series of researches. Mrs. B. had left us March 18; but several persons, among them my uncle Mr. Paul Janet, Dr. Charles Richet, the Messrs. Myers (of Cambridge), Dr. Ochorowicz and Mr. Marillier, having expressed a desire to witness a few of these experiments, we induced her to return to Havre, April 11.

"I was much concerned about the success of the experiments, for in my opinion they were made under faulty conditions. Till then I had not been able to produce sleep from a distance, save after training the subject for a considerable time—an hour a day, for 14 or 15

[1] See Part I, chapter iv.

days at least. Now, these gentlemen were to be in Havre two or three days after the arrival of the somnambule, and she must needs have lost in a month a good deal of her hypnotic habitude. To make good this deficiency, I endormed the subject several times a day. In this way I attained my object—that is, I produced a higher degree of sensibility, but at the same time brought about an untoward result. Mrs. B. was exceedingly fatigued; she had frequent headaches, which completely spoiled the normal phenomena.[1] Finally, after a few days it befell that she was in a state of almost continual drowsiness. Once she fell spontaneously into catalepsy, without any suggestion, two hours after having been awakened. It is my opinion that on that day, after two very protracted hypnotic seances, she was wakened awrong.

"However that may be, here is the simple record of the experiments in producing sleep at a distance, made during this third sojourn of Mrs. B. at Havre. April 14, being alone with her, I endormed her without touching her, but being in the same room. Sunday, the 18th, I was still alone, and for the first time in this series of experiments tried to endorm her from my house. I succeeded perfectly; she was asleep 10 minutes after I began 'thinking.' Monday, 19th, my uncle, Mr. Paul Janet, arrived in Havre I wanted him to see the subject previous to making any experiments, but he chose rather to ask Mr. Gibert to endorm her immediately from his house, for then nobody would be forewarned. Taken unawares, Mr. Gibert made the attempt at 4 o'clock; we found Mrs. B. completely endormed at 4.15. Tuesday, the 20th, Mr. Gibert again endormed her from afar at 8 o'clock P. M., in presence of Mr. Paul Janet, and by mental suggestion made her come to his house, as I will relate presently. Unfortunately, on the two days following, the 21st and 22d, for sundry reasons, among which the subject's fatigue and her headaches counted for a good deal, two experiments by Mr. Gibert to produce sleep at a distance were but partially successful; the subject was not endormed till half an hour later after a long resistance. But the same day, April 22, Mr. Gibert endormed her much more promptly in the evening, and on Friday and Saturday, at times set by Messrs. Myers, Ochorowicz and Marillier, I endormed the subject from a distance with full success and great precision.

"The gentlemen named left us on Easter Sunday, and it was absolutely necessary that the subject should be allowed to rest. I did not resume the experiments till May 4, when I endormed the subject from anear; but on the two days next following I again obtained sleep from a distance. A recital of these experiments would possess no interest, for it would be the same as the foregoing ones."

Mr. Janet concludes with a summary of the experiments on production of sleep at a distance, made whether by himself or by Mr. Gibert.

Of twenty-two experiments six failed; and of these six, three were made at the very beginning, when the somnambulic habit was not yet sufficiently strong; one was made later, but after an interruption of the seances for a few days; and two when the subject had held out

[1] These headaches could have been cured in a few minutes by imposition of the hands and by suggestion. [This note is apparently added by Dr. Ochorowicz.—*Translator.*]

for more than half-an-hour before she fell asleep. In short, sixteen successes, "definite and complete."

"Are we to suppose," asks Mr. Janet, "that the coincidence in these sixteen cases, though precise, was the result of chance? The supposition is, perhaps, slightly improbable. Was there all the time an involuntary suggesting on our part? The only answer I can give is, that with perfect honesty we took every possible precaution to guard against it."

All these experiments tend to prove not only action at a distance, but also:

1. The importance of "rapport," a relation that is brought about only by several consecutive magnetizations, and which puts the stamp of individuality on every successful experiment (the subject always knows whether it is Mr. Gibert or Mr. Janet that has endormed her from a distance, and the profundity of the state produced depends on the closeness of the "rapport");

2. The importance of sustained concentration of thought on the part of the magnetizer;

3. The absence of any perceptible difference in the degree of magnetization between action at the distance of a few paces and of a few kilometers.

(The same thing is seen in telephonic communications. The voice grows faint only when the distance is considerable, and even in that case the difference is determined by thickness of wires and by secondary circumstances—induction, electro-static capacity, etc.—rather than by the essential nature of the transmission. With a wire of copper instead of iron, with large diameter and well insulated, speech might be transmitted over thousands of kilometers. For us, the wire represents the "rapport.")

But the question of limits is as yet rather premature. Let us simply note the fact that the greatest distance mentioned in the foregoing experiments is ten kilometers.

If we suppose the phenomenon to be real, it is interesting to know what conditions are favorable or unfavorable to transmission from a distance. Mr. Aubin Gauthier[1] is the only magnetizer that has ventured to formulate them. According to him—

1. Inanimate bodies do not interrupt action from a distance;

2. Plants assist it;

3. Certain animals interfere with it;

4. A number of men may hinder it.

Finally, he adds that "in stormy weather it is difficult to magnetize not only from a distance, but even in presence of the subject."

It need not be said that I quote these assertions only as a matter of curiosity.

[1] "Traité Pratique du Magnétisme," p. 531. Paris, 1845.

PART III.

THEORIES, CONCLUSIONS, APPLICATIONS.

CHAPTER I.

THE HYPOTHESIS OF EXALTED PERCEPTION.

A. S. MORIN, in his interesting study,[1] says: "Communication of thoughts is one of the faculties oftenest noticed in lucid subjects, and often even it underlies several other kinds of lucidity that the observer fancies he finds, though in reality they do not exist. . . . There are very few somnambules that can discover your thoughts as they exist connected and formulate them in the self-same expressions that you have in your mind. Usually the somnambule takes some fragments of your thoughts while you are bidding him discover either matters in the past or occurrences at a distance, and then the lucid subject fancies that he has actually seen these things, though he has only read them in your mind. If after this you wish him to read your thoughts, however much you may concentrate your attention on what you mean to make him see, you will not succeed. Thus, the lucid subject steals your thoughts unbeknown to himself and to you, and when you propose to him as a performance to read your thought, he cannot do it. As regards this latter point there are some exceptions, notably the case of a cataleptic patient recorded by Mr. Puel; but they are very rare. [Morin, who wrote in 1860, could not, of course, know of the experiments recently made by the English Psychical Research Society, and by others.] And, above all, let not the reader jump to the conclusion that with a good somnambule he can at will penetrate the secrets of hearts. In case a lucid subject does read a few thoughts, he does so *only with regard to persons with whom he is in rapport*, and even that faculty, thus restricted, is

[1] "Du Magnétisme et des Sciences Occultes," pp. 185–188, and 283–289. Paris, 1860.

variable, intermittent, subject to illusion, so that the subject fancies that he possesses it when he does not, and flatters himself that he penetrates your thoughts, though he has discovered nothing, and gives out as a discovery the vagaries of his imagination."

Morin does not point out the probable causes of this variability. But these general observations are just, with this exception, that a well-behaved somnambule will never say that he sees this or that when he does not see anything. However, it is not difficult to test what he says.

Morin refers to thought-communication the apparent action of the will. He does not believe in a fluid, nor in any physical action, nor in direct will-action upon the organs of the subject. If the latter permits a limb to be cataleptized, or a sense to be paralyzed or hyperæsthesiated, that is because, after having divined the thought of his magnetizer, he himself influences his own body.

But Morin also rejects the hypothesis of a real transmission of thought; according to him thought is transmitted only by the usual signs. And to prove this divination by the outward signs of thought, he invokes in turn phrenology, physiognomy and chiromancy. As for phrenology, I really do not see what it has to do here, for no phrenologist hitherto has ever held that by touching the corresponding organs on the skull, one may divine *thoughts;* and besides, somnambules who divine thoughts do not touch the phrenological organs. Then, as phrenology itself is not a demonstrated science, we have a right to leave it out of account.

The same remarks apply to chiromancy. But, as regards physiognomy, or rather pathognomy (expression-signs in general), the comparison here is worthy of attention. There is no doubt that our thoughts, and still more our feelings and our character in general, are reflected on our countenance, that "mirror of the soul." "Among the signs and tokens that the exterior of the human body may thus manifest, there are some that strike every observer; the man addicted to drunkenness, for example, does he not bear upon his face the shameful tokens of his habits? There are other signs, the reading of which requires a good deal of sagacity. Lavater was gifted, in this respect, with a perspicacity that one might be tempted to regard as divination; he read faces as one reads a book. If the rules he laid down failed to constitute the science of physiognomy, or to develop physiognomists as clever as himself, the principles on which he based his system are none the less true, and the results he reached prove that all that is needed to complete his work is to formulate the method that instinctively guided him with admirable certitude."

Here I agree entirely with Morin. Physiognomy has a positive basis in a general determinism that applies no less to the development of organisms than to their stable characters, and which, with regard

to the matter in hand, may be thus stated: *Nothing in the exterior of a living organism is accidental.* We need but to know the causal relations that indubitably exist. But we are still far from that consummation, and I even believe that, the sooner to reach it, it were well, instead of formulating the laws of physiognomics—it is yet too early for that—to continue the study of *pathognomy*, to the revival of which Darwin lent the weight of his high authority.

The expression of states more or less fleeting, of diseases, pains, emotions, attention, and will-tendencies, is a far more convenient subject of experimental research than the expression of characters by fixed traits, which for a long time to come we shall be able to judge of only by a sort of intuition based on *unconscious experience.*

It is nevertheless certain that they who from childhood have been in the habit of observing, are able to read with close approximation to the truth a man's character in his physiognomy. In the case of sharp contrasts error, indeed, is almost impossible. The somnambule might possess the same faculty, and turn it to account in divining feelings, tendencies and habits.

And here is another point worthy of notice with regard to the divination of *diseases.* There is a certain work, now very rare and quite forgotten, that is unique in its kind. Its author was a distinguished physician, professor in the University of Freiburg, Dr. K. N. Baumgärtner, and its title is "Physiognomice Pathologica: Kranken-Physiognomik" (Stuttgart and Leipsic, 1839). It is a big quarto volume, with an atlas giving the physiognomic types of all the chief diseases. The figures, which are nearly of life size, are painted *by hand* and after nature, by excellent artists. Highly interesting to the physician is this crystallization, so to speak, of pathological signs that enable you to distinguish *by the countenance* a disease of the heart, for instance, from a disease of the uterus, and which thus prove that all is reflected in the face. Many experienced physicians possess this faculty of appreciation. It may be possessed in a certain degree by somnambules, in virtue of their lifelong unconscious experience, which, though in the waking state, amid the pressure of conscious acts, they perceive it not, may manifest itself in the psychic isolation of somnambulism.

So, too, with regard to the signs of emotions; and Morin should have noted in particular the modifications of the *voice*, which, even against our will, betray our sentiments, and especially our approval and our doubts. Divination of a thought depends sometimes upon these faint signs. "The physical is the expression of the moral," justly observes Morin; then he concludes:

"The lucid subject that penetrates one's thoughts does only what is done by the phrenologist, the physiognomist, or the chirognomist, only he sees a host of material signs that elude our sight and that are the complement of the indications furnished by examination of the

skull, the visage, or the hands. The lucid subject therefore possesses only means like those we possess, but his are much more extensive. Observation of the organs is everything. He is unable to explain, either to us or to himself, the value of each sign; it is a sort of language that he comprehends instinctively without knowing its principles; nor need that surprise us, for we all are acquainted with the first elements of that language, without having learned them, and though we are unable to formulate its rules. . . Suppose that at a party some one happens to talk of matters the mention of which angers one of the persons present, and that the latter lets his feelings find expression in his countenance; everyone will notice it, and it will be said, for example, that the man is angry, or meditating revenge, or that his hate is restrained by fear, and so on. But ask the company what were the physical signs that revealed so many things to them, and they will answer that they do not know, but that they are sure of the correctness of their judgment, and that the sentiments in question were manifested in such a way as to leave no room for doubt. In like manner, the somnambule that reads the thoughts of others cannot tell how they are manifested to him; all that he knows is that he *sees* them."

In short, as Morin himself puts it, "the question is simply one as to *the way in which somnambules see material objects.*"

Precisely here is the weak point of the theory.

In the first place, it is not well to leave out of view the sensations of hearing and smell; then, as the somnambule's eyes are shut, or, at least, he does not use them to divine thoughts, Morin's theory does but refer back an unsolvable problem to another not less so—"How do somnambules see material objects?" But that is another question. As for us, we do not care even to touch it; yet one might be tempted to suppose that Morin, who, to explain thought-communication, refers it to *somnambulic vision*, is able to explain for us the latter. But no! He rejects all known hypotheses and "confesses his ignorance."[1]

So we are back at our starting-point.

We would add that Morin's theory (though it may apply in certain cases) does not explain the experiments wherein the subject turns his back to the operator and has his eyes blindfolded; and *a fortiori* it does not explain any action from a distance.

Mr. L. Figuier[2] has broadened this theory, still accepting the same principle. According to Figuier, all is explained by an exceptional exaltation of the senses and of the intelligence in the state of sleep. The somnambule has no other sensations but those of our senses; but his perception being exalted, he perceives the faintest signs, voluntary or involuntary, proceeding from the magnetizer, and through these

[1] "Du Magnétisme et des Sciences Occultes," p. 271.

[2] "Hist. du Merveilleux," vol. iii., pp. 408–11. 3d ed. Paris, 1881.

divines the magnetizer's thoughts. "The transient exaltation of the senses of the magnetic somnambule," says he, "explains, we think, the phenomenon called by the magnetizers *suggestion* or *penetration of thought.* When a magnetizer announces that his somnambule is going to obey an order mentally expressed by him, and when the somnambule performs that feat—a thing, by the way, that is pretty rare—it is not impossible to account for the seeming miracle which, were it real, *would upset all our physiological notions*, and, indeed, all the known laws of animated nature. In this case, a *sound*, a *bodily movement*, a *sign of whatever kind*, an impression imperceptible to the rest of the company, suffices, in view of the extraordinary tension of the somnambule's principal senses, to enable him to understand, without any supernatural means, the thought that the magnetizer wishes to communicate to him. Thus, no more in this case than in others, is the magnetized individual privileged to break through the common barriers with which nature has hemmed in our powers."

Of course; "*Ad id sufficit natura quod poscit*," as Seneca said. But since that Stoic's day "the common barriers of nature," though they have not been broken through, have been set pretty well back, and besides, if there is any theory which might have checked the development of all the notions of modern physiology, assuredly it is the theory of insuperable barriers, had it been accepted before those notions were acquired. Who shall say just where those barriers stand? A metallic plate, for instance, can that talk like a human being? yea or nay? Mr. Bouilland—and he was no common man—said no; to accept such a fact were to upset all our notions of physiology. So said Mr. Bouilland right in the face of Edison's phonograph in full Academy, and he throttled the luckless interpreter of the famous American inventor, accusing it of ventriloquism.

But why and how must mental suggestion upset all our notions of physiology?

Not *all* of them, surely! I hope the theory of digestion, at least, for one thing, may stand unmoved. So, too, the theory of blood circulation, as well as the theories of respiration, reproduction, etc.

The *theory of perception* alone is at stake. But can it be that the existence of some subtile mode of transmission does away with the facts and the laws of a transmission that is visible and palpable? Did the invention of the electric telegraph do away with railroads?

No, we must not overstrain the maxim—a very wise one in its way—which recognizes certain natural limitations of all science. Let us not be more naturalistic than nature herself; let us leave to her the initiative of opposition.

In short the theory of Morin and Figuier, though these admit the *facts* of mental suggestion, does not account for those facts as a whole, and is hardly applicable to cases where there is anything like

definite transmission, many of which are cited by those authors themselves. Still, it is not to be denied that their theory might to advantage be developed so as to help explain a great number of mixed cases in which the *normal perception exalted* is combined with true transmission. Further, it must be allowed to possess this advantage, that it rests on an eminently scientific principle, that of referring the unknown to the known *as far as possible.* Only, I think it applies it amiss.

Anyhow, it is an evasive hypothesis. It turns the difficulty round instead of facing it.

Come we to theories that frankly accept the phenomenon.

CHAPTER II.

THE HYPOTHESIS OF BRAIN-EXALTATION WITH PARALYSIS OF THE SENSES.

IN the first place, we have to quote Bertrand. That eminent analyst did not, it is true, develop a complete theory of suggestion, but he did publish many clear ideas upon the subject that deserve to be mentioned.

Bertrand, too, does not believe in action at a distance, nor, in general, in any physical action whatever; he is the scientific father of the suggestional theory of magnetism. According to him, it is the subject that influences himself by imagination; *but the subject's imagination may be influenced by an extrane thought, even without any outward sign.* Thought is transmitted; will, not. Consequently, if the subject executes the order given, the reason is not that the magnetizer's will has acted on the subject's members, but that, having perceived the magnetizer's thought, the subject *consents* to execute it. "The Count of Lutzelburg, wishing to get light upon this subject, made the following experiment: He whispered in the ear of a witness that which he wished a somnambule to execute, and asked the patient if his thought determined her to act. 'I know it,' [the thought] she answered, 'and I execute that which you will. You willed, without telling me so, that I should sit down, and I obeyed.' . . . In general," adds Bertrand, "magnetizers nowadays [1823] seem to me to accept with inconceivable levity the opinion that the will of one man influences another man directly; but I know not any notion that

is more easy to overturn if one will but reflect upon it with some little attention. In the first place, there is nothing that is so inward to us as our will; will alone constitutes personality, the Ego." (Bertrand confounds here several phenomena. Personality is not the Ego, nor is the Ego the will; personality is a complex of all the psychic characters proper to the individual; the Ego is but a focus, a central point of this complex whole; the will is but a resultant of tendencies.) "And if the magnetizer's will took possession, as is supposed, of the person of the somnambule, the latter would be but an automaton actuated by springs extraneous to the magnetizer's second body."

Well, yes! It does often happen that the somnambule is nothing but an automaton. Bertrand, taught in the humanitarian school of Puységur and Deleuze, knew nothing of our modern magnetizers with their hurdy-gurdies. Furthermore, he was one of those who asked of patients the permission to do them good. "For the rest," he adds, "I know not how it is that the believers in this influence of the will *are not appalled by the consequences to which it leads.* According to them, a heedless somnambule, an agent actuated by an impulsion from without, may seize a dagger and bury it in the breast of his own brother, being powerless to withstand the will that dominates him, and being unconscious of his act till after the crime has been perpetrated. Fortunately, the case is not thus, and all the facts that have given rise to the strange opinion I am arguing against are powerless to prove more than communication of thought and the *limited* influence that such communication may have upon the determinations of the somnambule."

Here, again, Bertrand is in error. The experiment has not been made with mental suggestion, but many a time with verbal suggestion, and it is entirely certain that in states more or less near to monoideism the subject may commit a crime he is ordered to commit, and that without a suspicion of what he does, even after he has done the act ordered. Resistance is not possible save in full somnambulism, and may be suppressed by a few passes. About five persons in 100 will be unable to make any resistance. But the question of morality must not be mixed with questions of fact. What's true is true, and that is all. If we were to be "appalled by the consequences" in studying a problem, we should never reach new results, for everything that is new appals the conservative. Was not Jesus Christ crucified on account of his "dangerous novelties?" Neither Socrates nor Kopernik dreaded the consequences of a truth: they left to others the trouble of condemning them.

Fortunately, times are changed. To Mr. H. A. Taine is credited the following reply when some one reproached him with publishing doctrines that might be dangerous: "I never have thought that a truth may serve for anything."

But it may serve for something, only we must not trouble ourselves about it in advance. And I am certain that the sway of the magnetizer's will over the magnetized subject, *when it is rightly understood*, will be productive of far more good than evil.

"So to sum up," concludes Bertrand, "I think it absurd to suppose that in any case an extraneous will can act *directly upon the organs of somnambules*, and still less upon their determinations [the first phrase is correct, the second erroneous]; but it seems to me that a number of facts sufficient to produce conviction prove that not seldom somnambules have *cognizance* of the will, or the thoughts, of those with whom they are in rapport, and that this cognizance may determine them to act and produce upon them the same effects as though one had spoken to them. I will add that as this phenomenon results from the *sympathic communication* of the brain-movements of him who gives the order, the somnambule will all the more easily know the order given to him if it be accompanied by some gesture, which, *as it cannot be made without a greater movement of the cerebral fibers*, will help the communication: this is what is confirmed by experience in every case, and this is what I myself have observed. Besides, the opinion I express has been adopted by many magnetizers."

It is readily seen that the sharp distinction drawn by Bertrand between thought-transmission, which he accepts, and will-transmission, which he rejects, is a rather idle distinction. He had need to make yet another in order to be entirely right, namely, a distinction between direct action of will upon the peripheric organs, and transmission of will to the brain. As for the muscles, for example, it is nearly certain that without a local physical excitation of the tendons or the nerves, it is impossible to set them in motion by the act of an extraneous will; but that is not what is implied by the phrase "suggestive will-action." And once thought-transmission is granted, there is no reason for an outcry against those who believe that the tendency to any movement whatever may be transmitted as well as a purely passive and objective idea. As soon as you awaken a sentiment, you awaken also a tendency that is proper to it. Now, Bertrand does not deny the transmission of sentiments. Consequently, it being understood that the phenomenon cannot occur, *save by a reflex action of the brain*, there is no longer any need of drawing a hard and fast line of distinction between *will* and *thought*.

Bertrand has always in view a polyideic state of the brain, and that is what leads him astray. When there are many thoughts, they may resist the execution [of the order], and if it is executed, it is so only through the consent of those thoughts. But what if there are not many thoughts? When all opposition is done away by the state of aideia or of nascent monoideism, will not the thought "inoculated" [into the subject's mind] and made dominant by the very fact of its

isolation, determine execution? And it is just in that state that we must make direct experiments.

As to the *how* of the transmission Bertrand has hardly anything to say. But he seems to regard *exaltation of the brain* with *paralysis of the external senses* as an essential condition, and he very justly compares the sympathism of diseases, which he verified many times, with sympathism of ideas, which is more rare.

"Communication of ideas," he says, "is oftenest presented by *ecstatic* somnambules, and that, I think, is due to the fact that their state of moral *exaltation* could never have been produced without a considerable augmentation of the brain's sensibility, an augmentation that promotes, betwixt the brain of the somnambule and the brains of those around him, a sympathic communication like to that in virtue of which he feels, in other portions of his body, the pains of those in rapport with him." In another place Bertrand adds: "It has been seen that my will, though not expressed, had a true action upon the patient *in the state of paralysis*, and had no action that was instantaneously perceptible in the waking state."[1]

We shall see further on the importance of this simple remark.

CHAPTER III.

THE HYPOTHESIS OF DIRECT PSYCHIC ACTION.

BERTRAND'S sympathism, while it is not clear, has nothing mystical. It was a sort of *induction*, in the electrical sense of the word. A thought was supposed to induce a like thought, as an electric current induces a like electric current. Nothing passed from one brain to another brain. Was that an action at a distance—a very small distance (for Bertrand did not believe in anything else)? Doubtless it was, but Bertrand has not pronounced any judgment on the question. The transmission has not been explained.

Several magnetizers have tried to fill the gap by supposing *something that passes* from brain to brain, and naturally have attributed to this intermediary qualities now psychical, again physical, according to the bias of their several minds.

Let us consider for a moment the first hypothesis. My soul acts upon another soul. What more natural than to suppose a real trans-

[1] "Traité du Somnambulisme," etc., pp. 246–283. Paris, 1823.

ference of my thoughts? Such a supposition would cause no embarrassment to a spiritist. If my thought is able to move my body, and if my subject's thought can move *his* body, then to explain all I have only to suppose my thought to pass into his brain. How clear!

When the problem was to account for vision at a distance, the solution was simply that the soul of the subject, after quitting his body for a moment, went forth to see what was going on a hundred leagues away, and then came back and told what it had just seen.

It was a little awkward to leave the body so, without a soul. But the spiritists found a way out of that difficulty: the soul remained, the mind it was that made the excursion.

So with regard to transmission of thought. The soul (or mind if you will) not having any limits, as the body has, could easily stretch itself a little, so as to occupy for a moment an extraneous position, there perform whatever act was to be performed, and then double itself up and get back into its shell. Descartes recognized the impossibility of an action of thought upon extension (matter), but not upon another thought.

Consequently they might intermingle; and could anything surprise us in this affair, our surprise would be that this happened so seldom. We should rather look for a universal interchange. "Pass over to me your experiences and I will pass to you my hopes"—that would be a convenience! One man might go to school for the benefit of all, and then sell his ideas at so much a lot.

Unfortunately, the time is not yet come for this kind of commerce. We are even not quite sure whether a soul or a soul's thought can leave its body; or whether after it has quit the body it becomes more potent than it was just before. But that would have to be proved first of all.

Instead of supposing a direct passage [of thoughts], some spiritualists are pleased to allege an action equally mystical, but still more vague. "We know," (?) says Chardel,[1] "that obstacles and distances vanish for a lucid soul. It troubles itself no more about them: it gives itself up naturally to this new mode of investigation, and therein seems only to recover its manner of action *that is proper to it* [Chardel does not indicate the source of his knowledge], and which the loosening of the bonds of life has just given back to it."

It is as easy as to say, "Good morning!"

Others, without supposing a translocation or a mystical enlargement of the faculties, give us a glimpse of an almost physical "radiation."

"The mind,"[2] says the Grand Master of Spiritism,[3] "is not shut up in the body as in a casket; it *radiates* all around; therefore it can

[1] C. Chardel, "Essai de Psychologie Physiol.," p. 286. Paris, 1838.

[2] Or "spirit," *esprit.—Translator.*

[3] Allan Kardec, "Le Livre des Esprits," p. 185. Paris, 1862.

communicate itself to other minds,[1] even in the waking state, though more difficultly than in sleep."

That is pretty; but it would have to be proved that there exists an analogy between a soul and a lantern. And even that would not be enough, for a lantern only gives light, whereas a soul can command movements. True, a ray of light can make a Crookes radiometer to go round, but no one has yet determined what a ray of the mind is, nor what it can do.

The necromantic spiritists,[2] as we know, believe in a transmission of thought between embodied souls and disembodied spirits. "Spirits have only the language of thought; they have no articulate language," we are assured by Allan Kardec,[3] and we may take his word for it.

So, if a spirit has anything to say to us, it must needs employ an interpreter. The *medium* is the interpreter.

"It is the medium's spirit that is the interpreter, because it is connected with the body that serves to speak."[4] But in most cases this one intermediary is insufficient. "The *familiar spirit* is nearly always the one that acts as interpreter, to communicate to the medium the thought of the spirit evoked, when the latter is so exalted as not to deem it proper that he should come in person, or when other occupations hinder. Thought is communicated between spirit and spirit directly, and without the aid of spoken language. If you evoke a spirit that knows not your language, he transmits his thought directly to your familiar spirit, who translates it into the language that you know and that is familiar to you."[5]

Certain spiritualists have gone further still. They believe in the need of spiritual interpreters not only for a communication between a living man and an evoked spirit, but even between the magnetizer and his subject. "The influence that is exercised by one man on another man through the action of magnetism," says Dr. Billot,[6] "comes from an *auxiliary* either unknown or misknown, and only its presence can give the solution of the phenomena of magnetism."

This auxiliary is the world of spirits, good or evil—evil spirits particularly, the Marquis of Mirville assures us.

These authors take the exorcists' point of view: man cannot perceive the thoughts of men; therefore, if he seems to perceive them, it

[1] Or "spirits."

[2] *Spirites.* Here the author is speaking of spiritists of the Rochester-knockings sort: so to make the meaning clear I render the word as above, *necromantic* spiritists.—*Translator.*

[6] Billot, "Recherches Psychologiques," etc., vol. i., 12. Paris, 1839.

is because his guardian angel—or the devil—has whispered them to him.

We will not waste our time in examining these extra-scientific fancies. We would only remark that even if credulousness can carry men to these lengths, reckless incredulity is not a whit better. "Doubt," says Arago, "is proof of modesty, and has seldom hindered the progress of science. We cannot say as much of incredulity." For a striking proof of the result of a diseased skepticism, one need but read Mr. Mabru, "Laureate of the Academy of Sciences." That author wrote a book of 560 pages[1] to say that he sees nothing in magnetism (p. 5) in spite of all the letters he has written and all the conferences he has held. For him "magnetic somnambulism so-called does not exist any more than the fluid, and the phenomena that are attributed to somnambulism are nothing but pure illusion."[2] Puységur was fooled by his maid-servants, who simulated clairvoyance "to get higher wages," and so on.

He, too, supposes an interpreter for the phenomena of transmission, to wit, *a colluder*. "In order not to be duped by the clever tricks so often repeated in certain magnetic parlors, all that we have to do," says he, "is to *eliminate the colluder*. . . . There is no animal fluid, no *artificial somnambulism*, no magic, no sorcery; these pretended sciences possess in reality no scientific fact; and when, by means of immobility of body and strained attention, somnolence is produced in a sick patient or in a subject that is fatigued [but in fact this is done with healthy persons and persons whose senses are alert], the sleep is only common sleep. It possesses none of the miraculous properties of the so-called magnetic sleep. Often there are tricks of collusion; but these apart, it is utterly false that there exists between the *endormer* and his *subject* any relation, or any *psychic state*, except the ordinary relations of everyday life. Not only does the thing not exist, *but it cannot exist*."[3]

"There are errors," say Cabanis, "to which only wits are liable." Mr. Mabru has not this excuse, but he has another. La Bruyère says: "All the wit in the world is of no use for him that has none."

The other day Mr. Mabru was surpassed by a member of the Academy of Political and Moral Sciences. Mr. Mabru wished at least to learn; he asked for demonstrative facts. Mr. Desjardins, for his part, does not want to see anything, and will not suffer others to see. He condemns the study of hypnotism. He has not studied anything —that need not be said—but he is fully convinced that all the experiments in suggestion, whether of a therapeutic, a pedagogic or other nature, have been "pitiful failures." But they are hurtful and criminal, nevertheless. Not only the hypnotizers, but the hypnotized also, should

[1] E. Mabru, "Les Magnétiseurs Jugés par Eux-mêmes." Paris, 1885.

[2] *Id.*, p. 356.

[3] *Id.*, p. 483.

be punished, for "man has no right to abdicate his humanity and his free-will."

It is to be hoped that the honorable jurisconsult will not rest there. He ought to propose an enactment against those that sleep o' nights, seeing that it must not be permitted to a man to transform himself voluntarily into an inert mass and to abdicate his free-will. "As we might well expect," says Mr. P. Fauvreuil, "this eloquent protest has been approved unanimously and its author has been warmly felicitated. Mr. Arthur Desjardins has dealt hypnotism a stunning blow from which we hope it will not recover." [1]

Time will tell. Be it noted only that this took place August 13, 1886, thus in the 19th century, in France, in Paris, at the Academy.

CHAPTER IV.

THE HYPOTHESIS OF DIRECT PHYSICAL ACTION.

MOST magnetizers believe in the existence of a vital or magnetic nerve-fluid. A good deal of sport has been made of this fluid, and the subject, we must confess, invites such treatment. But those who have made many experiments are alone qualified to decide the question, and they tell us that often appearances are as though somewhat passed from the magnetizer over to the subject.

This subtile fluid is supposed to serve as an intermediary between mind and body. This it is that excites the muscles and transmits sensations to the brain ; this, too, it is that, under the impulsion of the will, *projects itself* outward and affects the nerves of the subject. Being of an eminently motile nature, if it is influenced by the environment as well as by the impulsions of the mind [or thought, *pensée*], it must reflect the man's personality, his feelings and sentiments, his will—it must be impregnated, so to speak, with the modifications of his mind. On uniting with another like fluid, though the same be individually different, it may transmit to it the same modifications. It is the fluid, then, that transmits thought, and the latter need not quit its body to act on another body.

This theory was first expounded by Lecat,[2] doctor of medicine and professor of physiology. His fluid is called the *animal fluid*, and it is

[1] *Soleil* newspaper of August 15, 1886.

[2] Lecat, "Traité des Sensations," pp. 154, 242. Paris, 1767.

interesting to find that as early as 1767 there was an effort made to account for certain mysterious transmissions. "This fluid," says Lecat, "being affected with the special character of a passion, carries the impression of it into the animal fluid of other individuals,"[1] for "sensations and impressions [or impresses—*pressions*] consist of modifications of the animal fluid, and these characters are communicated to fluids of the same sort, and are susceptible of change at every instant."[2] This fluid is an emanation, which the author, like most magnetizers, often confounds with odoriferous emanations. We quote one more passage:

"Once we recognize the evident facts that prove that the different characters of the animal fluid and of the vegetal fluids produce in the fluids of other individuals *emotions*, *changes of characters*, *considerable revolutions*, according to their consonance or dissonance, we shall have no difficulty in conceiving all the effects that result from their natural concurrence or from their conflict, of whatever sort they may be—intellectual, animal, or animo-vegetal."[3]

Such, in few words, is the theory of the magnetic fluid.

But why magnetic?

To answer that question, let us hear what is said of it by the chief advocate of this theory, J. P. F. Deleuze:

"A somnambule is sensible of [*saisit*] the will of his magnetizer, he executes what is mentally demanded of him. To understand this phenomenon we must consider somnambules as *infinitely mobile magnets;* no movement occurs in the brain of their magnetizer but is repeated in them, or at least they perceive it."[4]

But it was the more patent and more frequent phenomenon of *attraction* that suggested this analogy. Let the reader recall Bruno's experiment, which exhibits this phenomenon in an exceptional degree; but it is very common to see the subject's hand attracted by the approach of the magnetizer's hand, and following its movements. A magnet brought near to the subject produces the same phenomenon; and, though this action is not, properly speaking, magnetic, we know that such phenomena may well have determined the choice of the term "animal magnetism," which is not any worse than the term "electricity," as applied to certain well-known phenomena that have nothing to do with *electron* (amber).

Puységur, too, was struck by the analogy existing between a compass-needle and a mentally-suggestionable subject; but, as we shall see, he laid no stress upon this seeming analogy.

Deleuze makes yet another comparison: "We know," says he, "that if we place side by side two stringed musical instruments that are in unison, and twang the strings of the first one, the corresponding

[1] "Traité des Sensations," p. 154. [2] *Id.*, p. 549. [3] *Id.*, p. 242.
[4] Deleuze, "Hist. Critique du Magnétisme," p. 181. Paris, 1813.

strings of the second sound of their own accord. This physical phenomenon is like that which takes place in magnetism." [1]

According to this last analogy, the magnetic fluid carries the psychic vibrations as sound-vibrations are carried by the air.

And here is what this author says of action at a greater distance:

"Though it is very difficult to explain how the magnetic fluid can act from one apartment to another, most magnetizers are convinced of the reality of such action. I myself have made experiments that go to prove it. Nevertheless, that phenomenon being one of those that to me seem inconceivable, I invite magnetizers to examine it anew (1813), refusing to believe in it until they have verified it by their own experience. But light and sound travel to great distances, yet we cannot see in the motor agent that gives them forth a force sufficiently great to propel them rapidly, even through bodies. Whether light is an emanation from luminous bodies, or whether it is an undulation of ether, it is not easy to understand how the light of a coal or the flame of a candle makes itself visible instantaneously at a great distance through transparent bodies, or how the light of a star comes to us. Perhaps phenomena that we refuse to believe, because we have not observed them, are no more incomprehensible than other phenomena that do not astonish us at all, because we see them every day." [2]

He then adds this with regard to the conditions of magnetic action:

"In order that the fluid that goes out from me may act upon that of the man I magnetize, the two fluids must needs unite, must needs have the same tone of motion. If I touch with purpose and attention, and the one upon whom I wish to act is in a passive state or state of inaction, my fluid will determine the movement of his. There occurs then something like what takes place between a magnetized bar of iron and one not magnetized; when you pass many times, always in the same direction, one over the other, the one communicates to the other its motion or its virtue. That is not an explanation, but a comparison." [3]

"Once the nerves are permeated by a certain quantity of fluid, they acquire a susceptibility of which we have no conception in the ordinary state. Regard the magnetized individual as *in some sense a part of his magnetizer*, and you will not be astonished that the will of the latter should act upon him and determine his movements. That is all that I can say about the principle of magnetic action and will-influence." [4]

Evidently it is not an explanation. But, then, neither Deleuze nor any of his successors ever flattered themselves that they had explained the whole mystery. They have merely insisted upon the necessity of accepting a physical action—in their language "emission of the

[1] "Hist. Critique du Magnétisme," p. 180.

[2] *Id*, p. 85. [3] *Id.*, p. 91. [4] *Id.*, p. 93.

fluid"—in order to understand as well as may be possible the different phenomena of transmission. "The will," says Lafontaine, "cannot act upon another body materially. Our will acts only upon ourselves by producing a more active secretion in the brain and contractions in the plexus: hence the emission of a greater quantity of the fluid, and greater intensity in the action. . . . We can, therefore, justly say that the magnetic phenomena have one sole cause, the *vital fluid*, and that here, as everywhere, the will is but an accessory. . . . The belief that the will acts upon the magnetized individual is founded on one of the effects presented in the somnambulic state. A somnambule of developed lucidity sees his magnetizer's thought and obeys the mental order. That is a transmission of thought; from it the inference has been drawn that the will to which the subject is thus obedient is the cause; but that is a mistake: cause is confounded with effect. The transmission of thought is but the result of *the special state in which the subject is*. If the magnetizer is not in the proper state of health and strength; if he is tired, exhausted by any overdoing or excess whatever, he will be able to do nothing, or next to nothing [he can hypnotize, however], even though he bring to bear all the will-power he has. If, on the other hand, the magnetizer is perfectly sound and vigorous, and magnetizes perfunctorily, distractedly, without clearly defined intention, *he will produce, nevertheless, positive effects*. . . . To end the magnetic state, one must *demagnetize*, must free the subject or the member on which one has acted, of all the fluid one has transmitted to him, and however much the magnetizer may *will* the member or the magnetized individual himself to be restored to the normal state, that willing of itself is insufficient; one has, furthermore, to act *physically*, and if one does not that, or does it slightingly, the result often is distress that may involve serious consequences."

That last remark, apart from the theory of the fluid, is fully justified. We often hear of the injurious consequences following a magnetization. Now, never—and I bottom my remark upon an experience of 19 years—never can a magnetization do any harm if the conditions are duly observed; on the contrary, it must always be more or less beneficial; the least favorable case is where the effect is null. But experiments made hurriedly, for the sake of the effect, by strolling magnetizers or by hypnotizers that have not studied the literature of the subject, are very often harmful, and the main cause of the untoward results is an *insufficient demagnetization*. The beneficial effect of the magnetization is reduced by one-half, and sometimes serious mischief is done, by a *premature, a too sudden, or an imperfect awakening*.

"The advocates of will-influence," says the same author, "seem to rely upon another example to strengthen their cause. When a

magnetizer, from a distance and without any movement, endorms a subject that he is in the habit of magnetizing, or even when he magnetizes a person for the first time, they assume that the will alone acts. That is a mistake. The magnetizer, by concentrating himself in himself, produces the emission of the fluid, which hits [*frappe*] the subject and endorms him. Here, as everywhere, there is simply a projection of the vital fluid."[1]

This theory is simple, indeed. Were there such a fluid it would be very convenient for explaining facts; and oftentimes, especially in the therapeutic application of magnetism, *we must act as if the fluid existed.* But, in the first place, it is certain that in very many cases the intervention of the fluid is theoretically of no use; and that even where we are compelled to recognize a physical *action*, it does not prove the transmission, nor even the existence of a special fluid. In a word, the theory of the fluid is too simple in view of the complex facts, and too complicated in view of the simpler ones.

But herein Lafontaine is perfectly right, to wit: in maintaining that, action at a distance once admitted, a *physical* action must be assumed. Thought, as such, can neither *walk abroad* nor *radiate* elsewhither than in a brain to it belonging, or to which it belongs. But since the emission or transference, as well as the very existence of a special vital fluid, is incapable of demonstration, we must seek a more positive principle to elucidate our problem.

CHAPTER V.

THE HYPOTHESIS OF A UNIVERSAL FLUID.

THE general belief is that Mesmer was the propounder of the theory of a nervic, vital, or magnetic fluid, which, becoming detached from our body, is projected outward, is borne at need through space, and so on. That is an error propagated by those who have not read Mesmer, or have been unable to understand him. The theory we have sketched—and it is a very ancient one—was elaborated by the collective efforts of several of his *indirect* disciples, and in particular by the revelations of somnambules, who explained things as best they could. Finally, the authority of Deleuze, who himself points out this source, easily won popularity for a theory that anyone could grasp, that was comprehensible to the uncultured imagination, and

[1] "L'Art de Magnétiser," pp. 25–34.

that seemed to explain all. But it was in flat contradiction to Mesmer's doctrine, which was known only to his direct disciples. His course of instruction has never been published entire; but the extracts from it that were published by Puységur, as well as his Aphorisms, his Memoirs, and certain fragments that lay long unpublished, prove sufficiently how inexact is all that is said about him.

They show him to have been a mind profound as well as original, that may well have parted with the qualities of modesty and disinterestedness that characterized him at first, for he had to face a universal outburst of derision, the like of which surely never has been heard. Mesmer understood somnambulism better than Puységur, who in his enthusiasm exaggerated its value; in some respects he understood it better than the hypnotizers of our day, who do not know even Mesmer's disciples. At first people were fain to call him charlatan; then little by little they began to *discover* what he had discovered; they merely altered names so as not to compromise themselves, but they left to him the title of charlatan. 'Tis brutal, but the fact is thus.

I will state Mesmer's theory as far as it concerns the problem in hand:

Whatever is amenable to investigation may be expressed in two words: *matter* and *motion*. But to reach this conclusion we must efface from our cognitions the superficial impress given to them by the senses. "We acquire all ideas through the senses: the senses convey to us only properties, characters, accidents, attributes; the ideas of all these sensations are expressed by an adjective or epitheton, as hot, cold, fluid, solid, heavy, light, shining, sonorous, etc. For these epitheta substantives have been for convenience' sake substituted; soon the properties were substantified; we say heat, gravity, light, sound, etc., and lo!—the origin of metaphysical abstractions."[1]

These substances[2] were multiplied, personified. Hence ghosts, divinities, demons, *genies*, archei, and so on. "We still retain a certain number of these entities, which we must eliminate in order to get a clear view of phenomena. That is in general terms the end I purpose to attain" (p. 18).

Matter presents several degrees of *fluidity*. Water is more fluid than sand, for it can fill the interstices between the grains of sand; air is more fluid than water, for it can be diffused through it; ether is more fluid than air. It is difficult to determine where this divisibility ends, but we may suppose there are still many degrees of this kind, and that there exists a universal primitive matter, the graduated concentration of which constitutes all the states of matter. However that may be, it must be allowed, according to Mesmer, that all space

[1] "Mémoire de F. A. Mesmer, Docteur en Medecine, sur ses Découvertes" (1778). Nouv. ed. avec des notes du Dr. Picher Granchamp, p. 17. Paris, 1828.

[2] That is, these *substantified* adjectives.—*Translator*.

is filled, and we may well call the fluid which fills all the *universal fluid.* "Some physicists have already," says he, "recognized the existence of a universal fluid, but they have erred in defining its characters, in overloading it with properties and specific powers [*vertus*] that we cannot have cognizance of" (p. 22). This fluid exists though we feel not its presence. It is all around us, and with regard to it we are nearly in the same situation as fishes, which no doubt would be much surprised were one of themselves to declare that all the space between the bottom of the sea and the surface is filled with a fluid in which they live; that in this medium alone do they come together and go apart, and that it is the one means of their reciprocal relations (p. 22). "The universal fluid is simply the sum of all the series of matter in the highest state of division through the movement of its particles."[1] By it the universe is fused and reduced to one mass. All that can be predicated of it is, that it is fluid by pre-eminence, and consequently that it must in particular govern transmissions of motion more subtile than those effected by other and better known fluids. Water can give motion to a mill; the air transmits sound-vibrations, the ether light vibrations, the universal fluid transmits life-vibrations. Each of these series answers to a degree of phenomena, and the vibrations of each of these series cannot be perceived save in a corresponding degree of the organization (*i. e.*, of the aggregation) of matter (p. 24). Neither heat, nor light, nor electricity, nor magnetism, is a substance, but they are effects of motion in the different series of the universal fluid. While it is neither heavy, nor elastic, etc., this fluid determines the phenomena of gravity, of cohesion, of attraction, etc., as results of the re-actions of the motion communicated.

Properly speaking, there is in nature no attraction; it is only a seeming effect of communicated movements, and in general all properties, all so-called forces, are but *a combined result of the organization of bodies, and of the movement of the fluid in which they exist* (p. 25). This fluid it is that governs the mutual influences of all bodies; and as these actions and re-actions are, so to speak, symbolized in the mutual influence of the magnet and iron, we may give the name of universal magnetism to this general mutual influence. Nothing is exempt from this influence, which may be more or less inappreciable, but which theoretically has no limits. The heavenly bodies act upon us and we re-act upon the heavenly bodies, as well as upon the bodies around us. The property of the animal body that makes it capable of such action and re-action may be called, by analogy with the magnet, animal magnetism (Aphorism 8). Consequently, magnetism, whether the universal or the animal magnetism, is not a fluid, but an *action;* motion, not matter; transmission of motion, not an emanation

[1] *L'ensemble de toutes les séries de la matière la plus divisée, par le mouvement de ses particules.*

of any kind. No *displacement* can take place without *replacement*, for all space is filled (p. 39), and that presupposes that if a motion of the subtile matter is produced in one body there is forthwith produced a like motion in another similar body *capable of receiving it*, whatever the distance between them (p. 39).

"Considering," adds Mesmer, "that reciprocal action is general between bodies, that the magnet furnishes us with the model of this general law, and that the animal body is susceptible of properties analogous to those of the magnet, I hold the term animal magnetism, which I have adopted, to be fully justified. . . . I see with regret that this phrase is thoughtlessly abused; when one has familiarized himself with it, he flatters himself that he possesses the idea of the thing, whereas he has only an idea of the word. As long as my discoveries were regarded as chimæras, the incredulity of some savants left to me all the glory of the discovery; but since they were compelled to recognize its reality, they have taken to quoting against me the writings of the ancients, in which occur the phrases, 'universal fluid,' 'magnetism,' 'influence,' and so on. We have to do not with words, but with the thing, and, above all, with the usefulness of its application" (47).

Life is but a manifestation of a subtile motion, the stoppage of which is death. Among these subtile motions, sensations hold a chief place; all actions are the results of sensations (p. 49). The sense-organs correspond to different degrees of subtility in the vibrations that influence us, and they are not capable of being influenced save by a special sort of vibrations. But nerve-matter itself, as the supreme product of organization, is capable of being influenced directly by the most subtile vibrations of the most subtile matter: to wit, the universal fluid. This faculty, hitherto overlooked or misconceived, Mesmer calls the *inner sense* (*sens intérieur*).

Here I remark that this term recurs oft in the history of psychology, but in a different sense. Even Aristotle deals with this question. After him Albertus Magnus, Occam, Giordano Bruno, Cremonius, and many others, speak of a *sensus interior*, or even of *sensus interni*. But the term has been employed either in the sense of a *sensus communis*, bringing together all sensations, or in the sense of perception and consciousness of oneself.

Commonly the psychologists did but travesty the problem posed by Aristotle: "Must we suppose a sixth sense to see what the eye sees, to hear what the ear hears, etc.," or else (as in modern psychology) they gave the name "inner sense"[1] to the faculty of perceiving

[1] This faculty is what Sir William Hamilton calls the *vital sense*, synonyms of which are "subjective sensation" (Huxley), "cœnæsthesis," "vital feeling." It is, I believe, called by French physiologists *le sens de la vie*—the sense of life; the feeling we have of our own vital processes.—*Translator.*

the inward bodily sensations (*Selbstempfindungen*). The meaning given to it by Mesmer is different. He believes that nerve-substance in general and the gray matter in particular can be affected directly by the vibrations of the universal fluid. Herein he sees a source of vague cognitions, commonly inappreciable, particularly by man, in whom the sense-impressions and the development of reflection smother these faint perceptions; but in the animals, whose senses are less perfected, this *purely cerebral* sensibility makes up for the imperfection of the senses, and in many ways takes their place. It puts them in relation with all nature, enables them to divine directions in space, to forefeel terrestrial or atmospheric changes, and in general forms the sort of unconscious experience to which we give the title instinct. In man this faculty manifests itself only exceptionally, in normal sleep and especially in somnambulism, when the ordinary senses are in abeyance and there are no conscious thoughts to overpower it. "If it be true," says he, "as I shall endeavor to show, that we are affected by the enchainment of things and of events that succeed one another, we may see the possibility of presentiments and other like phenomena" (p. 50).

In the state of "crisis" the somnambule's senses may extend to any distance. All nature seems to be present to them. Even dictates of will are communicated to them without regard to any of the conventional means. These faculties differ according to the individual (p. 52); the most usual phenomenon is for a somnambule to see the interior of his own body, or even of others' bodies. But it is a rare thing to find all these faculties in the same person.

"How can a man receive the impress of a will not his own?"

"This communication can take place between two individuals in the normal state only when the movement resulting from their thoughts is propagated to the vocal organs, and to the parts that serve to express the natural or the conventional signs; these movements are then transmitted to the air or to the ether as intermediaries, and are received and sensed by the external sense-organs. These same movements, thus modified by thought in the brain and in the nerve-substance, being communicated at the same time *to the series of a subtile fluid with which that nerve-substance is in continuity*, can, independently and without the aid of air and ether, extend to an indefinite distance and report direct to *the inner sense* of another individual."

"From this a notion may be had of how the wills of two individuals can communicate by their inner senses, and consequently of how there may exist a reciprocity, an accord, a sort of understanding between two wills, which relation we may designate as *rapport*" (p. 75).

"As this sort of sensations are not to be had, save through the mediation of fluids as far excelling ether in subtility as ether excels common air, the means of expression fail me: it is as though I wished

to explain colors in terms of sound. I therefore must needs supply the deficiency with the reflections that may be made upon the constant *pre-sensations* of human beings, and more particularly of animals, with regard to the great occurrences of nature at distances all too great to be spanned by their ostensible organs ; upon the irresistible attraction that causes birds and fishes to make their periodic migrations ; finally, upon all the relevant phenomena furnished to us by the crisis-sleep [*sommeil critique*] of man " (p. 77).

These pre-sensations may relate also to the past or to the future, for to see the past is simply to perceive the causes in the effects, and to see the future is to divine the effects from the causes. Whatever *has been* has left traces ; so, too, whatever *is to be* is already determined by the concatenation of causes (p. 76).

But why is the state of sleep better fitted than the waking state to manifest these different transmissions? Mesmer answers that question with the utmost precision. The reason is twofold:

1. Because in sleep the sense-functions are suspended (p. 77), and the continuity of the common sensorium with the external organs more or less broken. "The impressions of circumjacent things, therefore, are made, not upon the external organs of sense, but directly and immediately upon the very substance of the nerves. The inner sense thus becomes the sole organ of sensations" (p. 78).

2. Because, in consequence of the senses being in abeyance, the psychic functions of conscious memory, of imagination, reflection, etc., which depend upon the senses directly or indirectly, are also suspended, and consequently the impressions made direct upon the cerebral substance "become perceptible by the very fact that they stand alone" (monoideism). "As it is the immutable law of sensations that the stronger effaces the weaker, the latter may be perceptible in the absence of the former. If the impression of the stars is not perceptible to our vision in daytime as it is at night, though their action is the same, the reason is, that in the day it is effaced by the superior impression made by the presence of the sun" (p. 78).

For individual transmissions from man to man we have to recognize two other conditions:

1. That of *rapport.* The special action between two individuals is facilitated by a sort of *accord*, by the production, natural or artificial, of a like *tone* of motion or of a like tonic motion, which makes a brain more susceptible of a vibration belonging to the same category (pp. 24, 75).

2. That of *education.* For the perfection of this crisis-sleep not only varies according to the process [*marche*] of the crisis, and the temperaments and habitudes of subjects, but also depends very much upon a sort of education that can be given them in that state, and on the way in which you direct their faculties; in this respect the sleep

may be compared to a telescope, the action of which differs according to the means of adjustment (p. 81).

In a state favorable to transmissions of all sorts man enters into relation with all nature, and we might compare him to a liquid whose surface, being in perfect equilibrium, reflects like a mirror everything in the universe, faithfully pictures all objects. But fancy that surface ruffled by all sorts of shocks (impressions made upon the ordinary senses), and you shall see the liquid agitated by innumerable undulations and re-actions, and the reflection of objects will disappear.

But, plainly, it is but seldom that all these conditions of cerebral perceptivity are combined. Sundry observers, impressed by what they saw in exceptional cases, have supposed that they could at will develop lucid somnambules. They forgot that it is always in the state of sleep that dreams are commingled with true sensations. They confounded together magnetism and somnambulism, and so exposed both to the ridicule of men of sense.[1]

Mesmer does not hide from himself the fact that in spite of all the reserve one may exercise with regard to so delicate a subject it will be hard to convince those who have not themselves verified the phenomena. "Suppose," he says, "a people that of necessity must fall asleep at sundown, and that never awake till sunrise: such a people would have no conception of the magnificent spectacle of the night. Were one to tell them that there are among them men in whom this wonted ordering of sleep and waking is disarranged, and who, awaking in the night, have descried at infinite distances innumerable luminous bodies, new worlds, so to speak, one would doubtless be treated as a visionary because of the vast difference between the opinions held on the one side and on the other. Such to-day, in the estimation of the multitude, are those who maintain that in sleep man has the faculty of broadening his sensations" (p. 80).

"In the memoir I published in 1779," says Mesmer again, "I made known the reflections I had made many years previously upon the *universality of certain popular opinions*, which, as I believe, are the results of the most widespread and the most constant observation. Thereanent I said that I had undertaken the task of inquiring what of useful and true might be contained in old-time errors; and I felt warranted in asserting that among the vulgar opinions of all times [as imposition of hands, visions and oracles, influence of certain metals, mystic action of man on man, evil eye, power of taming animals, communication at a distance, presentiments and simultaneous sensations, influence of yearning and of prayer, transmission of health, strength, disease, etc.] there are few, however ridiculous, however extravagant they may seem, that may not be regarded as remnants of truths primitively recognized" (p. 3).

[1] "F. A. Mesmer," p. 79. By Dr. Kerner. Frankfort-on-Main, 1856.

And as certain of these processes, by a too scrupulous observance (p. 44), by a blind application (p. 44), seemed to recall ancient opinions, ancient practices that have justly been regarded as errors (p. 89), "most of the men devoted to science and the healing art have considered my doctrine only from this point of view: carried away by these first impressions, they have neglected to study it thoroughly. Others, actuated by personal motives, by professional interest [*interêt de corps*], have refused to see in me aught but an adversary that they must crush. To that end they employed first the so powerful weapon of ridicule, and the no less effective and more hateful one of calumny; at last they spread broadcast copies of a report[1] that is destined to stand for all time as a monument that will insure little of honorable fame to the men that dared to sign it. Other persons, convinced at last, whether by their own experience or by that of others, have become enthusiasts, and have indulged in such exaggerations as to render all the facts unworthy of belief. Hence have resulted, for the weak and uneducated multitude, illusions and groundless fears. Such hitherto have been the sources of public opinion adverse to my doctrine" (pp. 89, 90).

Hitherto! Yes, as late as 1886.

"I willingly submit my theory to criticism, declaring that I have neither the time nor the will to reply. I should not have anything to say to those who, incapable of crediting me with straightforwardness and disinterestedness, would think only of attacking me with purely hostile intent; and I should be pleased to see men of greater talent discover principles more solid, more luminous, men of larger mental endowment than myself develop new facts"—they have discovered new names—"and by their ideas and their researches render my discovery more interesting still. It will be enough for my fame that I have been able to open a vast field for science, and that I have in some measure traced the route of this new career" (p. 92).

Such were the opinions of the illustrious "charlatan."

We may take exception to several points of this hypothesis, and, indeed, I shall endeavor later to present the facts in a slightly different aspect; but it will be allowed, I think, on comparing Mesmer's ideas with those of his successors, that his is the only theory worthy of the name.

How far removed we are here from the crudities of the magnetizers with their fluid running hither and yon! which *goes around walls* and floats through the air to *hit* the predestined subject and to set itself up within his body! Heedless of their master's admonitions, they have hypostasized, substantized an *action*, creating a new metaphysical entity, whereas he wanted to free us from the ancient ones.

But how far removed we are also from the academic commonplaces

[1] 1784.

that attributed all the phenomena of magnetism to imagination, imitation, and jugglery! Fortunately, prejudices pass away, and experience remains. Undoubtedly we are beginning to go back to the fountain-head. Dr. Despine, Jr.,[1] published in 1880, that is 200 *years after Mesmer*, the following reflections:

"*Explanation of the phenomenon of thought-transmission.* Action from a distance upon the psychic phenomena of somnambules being no longer matter of doubt, let us try to explain it by means of natural agencies. Let us remark, in the first place, that the expression 'action at a distance' comes from the belief that there is vacuum in nature. Now, that is not so at all."

Before I proceed with the exposition of Mr. Despine's views, I will observe that though he is perfectly right in rejecting action at a distance in the absolute sense of the term, that is, across a vacuum, he goes a little too far in affirming the non-existence of a vacuum. That was Mesmer's error, for he, too, regarded the universe as absolutely *full*. That supposition is incompatible with the idea of motion such as is necessary for explaining any transmission whatever. One can, indeed, conceive the motion of a sphere turning on its axis *without displacement;* but when there is question of transmitting any motion, we must postulate a free space, a *shock* communicated through this free space, consequently a vacuum. To assume a medium more and more elastic, and which, because of this elasticity, opposes no obstacle, will not serve; for when you assume a matter to the last degree subtile, you still must ascribe to it *particles* separated from one another by empty spaces. Either a vacuum exists or there is no motion. Motion being change of place, there must be a place in order that place may be changed. From this there is no escape. Whether it is thus with "the thing in itself" of Kant, I know not; but what I do know is, that one puts himself under an illusion if he thinks he can comprehend motion without a vacuum; a motionless movement, if I may be allowed the expression, there may be—but that does not help; a transmission of motion, no.

But that is a question that is independent of the mystic action at a distance. Vacuum may exist, and action at a distance across vacuum may not exist.

Mathematicians have often puzzled their brains calculating the actions and re-actions that must take place between two material points separated by vacant space. It is labor lost. Between two material points separated by vacant space there is neither action nor re-action. Universal attraction as an occult property of bodies is a senseless idea, infinitely more difficult to comprehend than the transmission of thought. It is not I who say this: it is Newton. The

[1] Dr. P. Despine, fils, "Etude Scientifique sur le Somnambulisme," pp. 222–229. Paris, 1880.

theory of Newton has been brutalized, idiotized, as that of Mesmer has been, by men who could not understand the necessity of subtile ideas for subtile causes. Newton himself—and here Mr. Despine is perfectly right in quoting him—rejected action at a distance: "That brute matter (or matter of any sort) should, without the intermediary of any other thing that is not material, be able to act, to operate upon other matter without mutual contact, is incomprehensible. That gravitation should be inherent, essential to matter, so that a body may act upon another body at a distance in space, without the intermediary of something whereby their activity"—in other words, their motion—" may be transmitted from the one to the other, seems to me so great an absurdity, that no man, I believe, who is competent to think of philosophic matters, can ever fall into it."[1]

And yet that is the opinion of the majority of scientific men nowadays. But let us go back to Despine's analysis:

"The researches of modern physicists confirm Newton's view in so far as they prove that there is no vacuum [again the same confusion]; that space is full of a matter that is eminently subtile, called ether, whose attributes are not only transmission of electricity, and transmission of terrestrial magnetism, but also transmission of light and heat. [A matter eminently subtile means a matter eminently rarefied, and if a thing is rarefied that means that there is vacuum between its particles.] The vast interstellar spaces then are not regions of vacuum and of isolation. We find them filled with this medium which extends everywhere, so that when a molecule of hydrogen vibrates in Sirius, the medium receives therefrom an impression; but so great is the distance of that star that this impulsion takes three years to reach the earth. And yet that distance *in no wise alters* the vibrations transmitted." [That is another question. No one has been in Sirius to compare them.]

Mr. Despine then quotes from Herbert Spencer a passage of which I will repeat a part:

"The discovery that matter, apparently so simple, is, in its inmost structure, astoundingly complex; and that other, that its molecules, oscillating with almost infinite rapidity, propagate their impulsion to the surrounding ether, which transmits them to inconceivable distances in times infinitely small, lead us to this still more wonderful discovery, that *molecules of each kind are affected in a special way by molecules of the same kind that exist in the remotest regions of space.*"[2] That is Mesmer's idea.

[1] Our author does not locate the passage in Newton's works, and the above is but a version of the French version.—*Translator.*

[2] Diligent search has failed to discover the original of this passage in H. Spencer's "First Principles;" the translator must therefore content himself with a version of the French translation of it.

Mr. Despine quotes also Mr. Bertrand, of the French Academy, with regard to the existence of ether and its action upon the phenomena of light, electricity, etc. Then he adds:

"Why should it not be of equal importance in organic nature? May we not reasonably suppose that that which in this universal medium is the principle of light, electricity and heat, may also, when united with nerve-matter, be the principle of life in animals possessing a nervous system, and consequently the principle of activity of that system and of its various functions? When we reflect that this system is not absolutely necessary to life, inasmuch as plants and the lowest animals are without it; when we reflect that light, heat and electricity, that is, the principal manifestations of the ether, are necessary to life, seeing that wherever they are insufficient vegetal life and animal life are impossible, and that life is all the more active the more potent these manifestations are; when we reflect upon all this, have we not a right to conclude that the principle of life in organized bodies really consists in these three manifestations of the ether, and that the nervous system is needed only to regulate [*présider à*] the specialty of each function as the ether puts the same in action? This hypothesis seems to us so reasonable that we take the liberty of submitting it for the judgment of the learned."[1]

I do not well see, I confess, the advantage of this transfer to the ether of the *principle* of nervic and of general organic activity; I do not think it is made thereby more comprehensible. So many things are saddled upon that long-suffering intermediary! Mr. Despine attributes to the ether light, heat, electricity, terrestrial magnetism, gravitation, molecular attraction, chemical affinity, the functions of organic life and those of automatism, finally, the functions of the brain. There remains little, I think, to dispose of. Yes, there is Providence; but that has been attended to. Spiller[2] attributes to the ether not only all these things, but Godhead too. "The Ether is God," says Spiller. I see no difficulty in going so far, but why halt there? Let us call light the Son and electricity the Holy Ghost, and everything will be explained. The only thing to be accounted for then will be *how* the Ether formed organisms and watches over the human race.

Let us return to mental suggestion.

"From these data," continues Mr. Despine, "we see how brain activity, which governs psychic manifestations, may, under certain conditions of impressionableness [what are they? a theory of transmission ought to define them], be echoed in an effective way in the brain of another individual *by means of the ether*, may therein determine an activity of the same kind, and therein call out similar

[1] "Etude Scientifique sur le Somnambulisme," p. 285.

[2] "Gott im Lichte der Naturwissenschaften."

instinctive elements, thoughts, mental representations and volitions. Every psychic act, unquestionably, has for cause a cerebral modification of vibrations, a special mode of activity in the gray-matter cells of the brain. True, these vibrations are not capable of impressing, by the intermediation of the ether, similar vibrations on neighboring *sound* [?] brains. Yet, however faint these vibrations, they nevertheless are propagated outwards, though they hit [*frappent*] those brains without effect. But suppose that among these brains there is one that is in such a state of impressionableness as to be influenced by the ether-vibrations produced by the activity of a sound brain, and suppose that these vibrations produce in this impressionable brain identical vibrations, then the activity of this organ will certainly give rise to similar thoughts. Thus is explained naturally thought-transmission and transmission of will from one individual to another, without external signs. If this action is rare, that is not because of the mode of action of the ether fluid nor of the laws governing that mode of action—two things that do not change; it is because of the *special state* in which the nervous system may be influenced by this faint action—a state consisting particularly in an *extreme sensibility* of that system, and which is abnormal, pathological [?], and, fortunately, rare. The action of the agent is always the same; the thing that varies and that makes the phenomenon rare is the state of the nerve-organs that receive the action of the agent."

True, but rather vague.

"By this cause of transmission from a distance—a transmission that is undoubted, and which has to be held in reserve simply because it has not yet found popular acceptance—is explained not only the transmission of thought in somnambules, but also the fact that persons whose nervic constitution is vigorous, whose cerebral activity is energetic, and whose will is strong, are better magnetizers than persons of feeble constitution. So, too, we explain nervic contagion, which Bouchut[1] believed to be a fact—a contagion that under certain

[1] Here is a significant passage from this eminent observer: "One might say that in certain cases, notably with regard to convulsive neuroses, there exists a *direct physical action* of the patient upon the man in health, by a nervic emanation the influence of which produces at a distance the convulsive state, for it is difficult always to explain the fact by imitation, as imitation is commonly understood. However that may be, contrariwise to what we see in other modes of contagion which we think we understand, attributing them to miasmata, cholera for example, we know nothing of the cause of epidemic neuroses, as chorea or hysteria; we know no more about their contagional principle, if so be that there is one, than we do about the vehicle in which it is conveyed. It is easy to frame hypotheses about it, but impossible to demonstrate the nature of the contagion principle. . . . The action of this nervic contagion is exceedingly powerful and almost without bounds. It acts upon men and upon animals, at every period of life, but particularly in youth, and its influence is greater on woman than on man. It shares at once the properties of contagion, in that there

conditions propagates afar the phenomena somatic and psychic that characterize the different epidemic insanities; so we explain moral contagion, as also the ascendant that strong minds exercise over weak." [But if they "hit without effect" sound brains, how can the vibrations of the ether transmit all this?] "So we explain why the processes of magnetization—passes made whether in contact or at a distance—are able to produce the different phenomena called magnetic. So we explain why it is that the organs that have been rendered highly impressionable by disease, and the organs best supplied with ganglia and nerves, as the head, epigastrium, neck, arms, finger-tips, are the parts most readily impressed by passes" [but then it is the number of nerve fibers that explains all this, not the ether theory]. "Finally, so we explain the very remarkable action of certain individuals' will upon other individuals, without any outward sign—an effect that we see exhibited very strikingly in the case of Castellan, condemned at the assizes of Draguignan" (227).

A little farther on the author gives as the cause of this special impressionableness of mentally-suggestionable subjects, "neuropathic and hysteric affections and anæmia."

It is usual for hypnotizers to confound these conditions with hypnotic sensibility, which is a primordial character independent of all disease. A person may be eminently sensitive and yet entirely healthy. Only it is easier for a hypnotizable person to become hysterical than for another person; or at least in the case of the former the hysteria assumes the convulsional character of the major hysteria. Neuropathics generally have no greater sensibility than healthy persons. Among the patients under the care of Dr. Aug. Voisin at the Salpêtrière, Paris, we found but 28 per cent. sensitive: among persons in health the proportion is 30 per cent. As for anæmia (another error propagated by Prof. Heidenhain!) it is rather an unfavorable condition: at all events, an anæmic *brain* is not necessarily more impressionable than an hyperæmic one; I am inclined to hold that it is less.

Mr. Despine closes with the following reflection: "If neither nervic fluid nor magnetic fluid intervenes in the phenomena of animal

is apparently a contagional agent, and of imitation by reason of its moral and mental character." (Bouchut, "De la Contagion Nerveuse," etc., p. 14. 1862.)

I quote the above passage from J. Rambossom's "Phénomènes Nerveux, Intellectuels, et Moraux, leur Transmission par Contagion," pp. 200, 201. Paris, 1883. This author does not speak of mental suggestion, but he formulates a law of the transmission of expressive motion (*mouvement expressif*) in the following terms: "A cerebral or psychic motion may, in traversing different media, became purely physiological, then physical, once more physiological, and finally cerebral or psychic, without changing its nature, *i. e.*, while still retaining the power of reproducing all the phenomena that are appurtenant to it" (p. 187). This law may be regarded as the generalized formula of psycho-physical theories. See the next chapter.

magnetism so-called, as the old theory had it, the universal fluid does positively intervene, if not as the direct cause of the phenomena, then at least as the agent for transmitting the mode of activity of one person's nervous system to the nervous system of another person."

In short, between the theory of Mr. Despine and that of Mesmer, which he knows not, there are only a few differences of detail, to the advantage of the latter if I am not mistaken.

Mesmer held, like Spencer, that the particles of a given matter are affected principally by particles having like motions, and, guided by this thought, he conceived a series of motions of progressive subtility, and a series of states of matter of progressive rarefaction—solid, liquid, gaseous, etheric, more subtile still, the state of the universal fluid or primordial matter, and that too, presents degrees, but to us they are unknown. In short, he made a division of Nature's work, and distinguished the universal fluid, which he regarded as the medium of life-vibrations, from the ether, to which he assigned mainly the light-vibrations. In sooth we know nothing about this whole organization, but as the matter is entirely under our own control, we can allow ourselves the luxury of several series; that is at least fairer than to lay the whole burden upon the back of one fluid. Then, I believe that there are in nature no absolute limits, and I prefer Mesmer's graduation to the fluid, doubtless imponderable, of Mr. Despine, that is to say, of the majority of modern physicists. That fluid, which is but an absolute negation of "ponderable" matter, constitutes a species of matter absolutely the reverse of everything we know of ordinary matter, and, let us say it frankly, inconsistent with common sense. The particles of ordinary matter attract one another, those of the ether repel, and so on. It is a tissue of phantasy. The ether is an *imponderable* fluid. But if "fluid" means anything, then "imponderable fluid" is nonsense. A fluid, that is, something that can flow, must be *impelled* by something, and consequently must *weigh* upon something. Again, the molecules of the ether, we are told, are attracted by ordinary matter, and when one body is attracted by another body, it *weighs* upon it. Then, the ether cannot fill *all* space, precisely because it is *rarefied.* Finally, if this is to explain for us attraction and ponderability, it cannot itself be either ponderable or imponderable, since it is only by a relation between it and ordinary matter that these qualities are manifested.

In a word, I understand the necessity of a *gas* more rarefied than the gases we now know, *i. e.*, more rarefied than hydrogen (there are perhaps many such, for all I know); but I do not understand a matter that is not matter, a rarefied body that does away with vacuum, a *deus ex machina* explaining everything, himself incomprehensible. I prefer my ignorance to such science. And I beg the mathe-

maticians not to imagine that they can discover anything outside of the relations founded on experience. A psychologist can understand this. He can value as highly as you please the four, five, or *n* dimensions shown him by means of abstract symbols, but he confesses frankly that *three* dimensions he can indeed imagine for himself, but no more. Were Zöllner still alive, he, no doubt, would explain thought-transmission by saying that it takes place across the fourth dimension, and we should have one theory additional.

In the lack of that, it only remains that we mention one theory more, and that simply in order to make a transition from the foregoing hypothesis to our own. This transition we find in Puységur's theory.

CHAPTER VI.

THE HYPOTHESIS OF A PSYCHO-PHYSICAL TRANSMISSION.

THE sympathetic wizard (*sorcier*) of Busancy, who was so deeply interested in mental suggestion, is worthy of mention here. He was a soldier,[1] and disposed to cut the knot of a problem. The series of Mesmer's universal fluid had some difficulty in effecting a lodgment in Puységur's cranium, but he was a marquis all too courteous to bear a grudge against his master on that score. Rather does he charge himself with incapacity for metaphysics, and confess that, after having for two months attended Dr. Mesmer's theoretic course, he knew about as much of magnetism as before (p. 30). But theory mattered little to him. "Increase the number of experiments," says he, "and you will come upon a theory; else you will lose your time. Had we been obliged, in order to recognize the well-known phenomena of electricity, of the magnet, and of galvanism, to wait till we should agree as to their causes, there is reason to believe that we should to-day have neither lightning-rods, nor compass, nor Voltaic pile. Is there an electric fluid, a magnetic fluid, a galvanic fluid?" (p. 26.) He does not know whether there is or not; but what he does know is, that in order to act upon Victor or Magdeleine he did not need to have any knowledge of poles, or even to believe in the existence of a fluid. "So I took care to choose rather a certitude gained through

[1] Puységur was *maréchal de camp* of the royal artillery corps. The quotations that follow are from the work published in 1807, entitled "Du Magnétisme Animal Considéré dans ses Rapports avec diverses Branches de la Physique Générale."

experience than the hypothetic probability of a magnetic fluid, the existence of which no physicist has ever been able to verify" (p. 35).

Then he passes in review the phenomena of heat, of fire, of the electric machine, of light, of the Voltaic pile and of galvanism, of the magnet, and of the *sorciers*,[1] and by a series of comparisons and reflections of the utmost lucidity, comes to the conclusion—quite opposed to the dominant ideas of his time—that heat is but the *effect, perceptible to the senses, of the transmission of a motion* (p. 37); and that, consequently, "caloric has no existence" (p. 38); that the cause of the magnetic properties of the loadstone results solely from a "tonic inner motion (*mouvement tonique et intestin*) in the iron, *of a kind much like that recognized as existing* in the Voltaic pile" (p. 71). Ampère's theory! Finally, that it is all "transmission of motion."

Puységur is incomparable in his deductions from an experiment in thought transference compared to an experiment with an electrostatic machine. He poses two problems: To light at a distance a bit of amadou by the aid of the electric spark; and to act mentally from a distance upon his brother, who is at Versailles. "I performed an action, that of turning the crank of the machine, I not stirring from where I stood; the action of necessity had its indispensable result, which is, to communicate motion; from this I concluded that no bit of amadou in the world can be set on fire save by *the transmission of a communicated motion*" (p. 46). "My brother is four leagues away, at Versailles. Let us see how I may transmit motion to him. Nothing can be simpler. I recall his image and I think of him. 'Mysticism and witchcraft?' By no means: it is the sanest kind of physics. Is not every human act preceded by the volition to execute it? Is not the volition itself preceded by the thought that it can be carried out? That thought then is the motor; hence it is as regards me what the glass plate is as regards the electric machine. 'And you think you can produce some effect upon your brother by the action of your mind?' Certainly not. He would in that case be less sensible of the action of my mind than you, not being insulated, would be of the action of the revolving plate of an electric machine" (p. 53).

So, then, one must be "insulated" in order to feel a transmission of motion otherwise imperceptible. Imagine a series of ivory balls suspended by threads and contiguous to one another. If I hit the first, the last that very instant leaps out. If I strike the end of a bar of steel with a hammer, it becomes magnetized. The particles cannot leap out, nevertheless they are put in motion; this "inner motion" (*mouvement intestin*) is accelerated and regulated in some unknown way, and lo! the bar is *magnetized*. In like manner, by producing an

[1] Probably practicers of "Bletonism," named from Bleton, a Frenchman, who claimed to possess the faculty of perceiving subterranean waters by sensation.—*Translator.*

inward shock of my will (*en effectuant un choc intérieur de ma volonté*), I transmit motion that may be reverberated by a being at a distance (pp. 33, 52).

This, it is seen, is Mesmer's theory simplified and popularized, *minus* the universal fluid, which Puységur cares little about, and *minus* the remarkable precision of the founder of magnetism.

This theory was lately propounded by Dr. Perronet under the name of *undulationism*. He formulates it very briefly, thus:

"Suggestion is a phenomenon whereby an individual transmits to one or to many other individuals his own thoughts, whether conscious or unconscious, by materializing them in the forms of the objects represented by them, and passing through this series of intermediate phenomena:

"1. Nerve-undulations of central origin and centrifugal in direction, which undulations are produced by an unknown mechanism in the organs that serve as a ground for his psychic faculties;

"2. Undulations at the periphery of his body, fibrillary contractions or other kinetic phenomena that are usually unconscious;

"3. Undulations produced in the cosmic medium by the foregoing motions;

"4. Shock to the nerve-extremities of the recipient individuals from these cosmic undulations, which produce in the psychic centers of those recipients the final undulatory phenomenon, translated by the real perception of the object signified by the thought." [1]

And now let us put all these theories aside and attend only to the facts. I will endeavor to make them intelligible as far as may be in the present stage of our researches. And you, gentle reader, keep an eye upon me, lest I broach some absurdity—a thing quite possible in so perplexed a question, and that happens oft to those who do not spare others.

[1] Claude Perronet, "Du Magnétisme Animal," pp. 60, 61. 1884.

CHAPTER VII.

THE ELEMENTS OF A SCIENTIFIC EXPLANATION.

BE it observed at the outset :

1. That the suggestion called mental is a highly complex phenomenon, which for that reason cannot be explained by one simple principle ;

2. That even with regard to a determinate and isolated fact, the theory must necessarily be bifarious : psychological and physical ;

3. That in all phenomena of this sort we must consider, on the one hand, the conditions pertaining to the operator, on the other the conditions pertaining to the subject.

This stated, let us have an understanding as to the general purport of a scientific explanation.

Explaining means nothing else but *reducing the unknown to the known ;* and there is but one way of doing that, to wit, by pointing out *the conditions on which the phenomenon appears, and without which it cannot appear.* That is all that one can do ; it is also all that is required. We must not suffer ourselves to be under the illusion that adequate knowledge is attainable of anything. We ascertain the conditions of phenomena, we state these as well as may be in *laws* that are simply a generalization of our observations : that is all. That is the whole of science.

If we would define the conditions of a phenomenon, we must first *describe* it, *analyze* it, so as to circumscribe its contents and assign it a suitable place among other phenomena. This we have endeavored to do by treating separately the different kinds of psycho-physical transmission. It follows that mental suggestion proper must be studied in connection with sundry phenomena of physical transmission, which, by approaching it step by step, elucidate it. Furthermore, as we have seen, very many phenomena that have been attributed to physical or mental transmission, are only facts of apparent transmission.

This *apparent transmission* may, according to the nature of the case, be explained :

1. By a pre-established harmony between two associational mechanisms mutually independent, but depending upon a *psychic medium ;*

2. By a presumption[1] based on the ordinary sensations of sight, hearing, smell, and touch.

These sensations, which betray our organic or our psychic state, can be perceived or even realized by the subject in proportion to :

[1] On the part of the subject. From the sense-impressions received by him in any way from the magnetizer or the bystanders, he infers the purport of the intended mental suggestion.— *Translator.*

1. His *unconscious experience*, a faculty belonging to us all, and which tells especially when conscious reflection is in abeyance;

2. His *ideorganic associations;* these may reveal the signification of influences more or less unnoticed in the normal state;

3. His *ideoplasty*, which realizes the thought suggested by unconscious experience and by ideorganic associations;

4. His hypnotic and magnetic training, which facilitates the cooperation of all the foregoing agencies.

It follows that apparent transmission will be favored:

1. By exaltation of the senses;

2. By exaltation of the intelligence;

3. By isolation of the senses and the intelligence, which allows the whole power of attention to be concentrated in one chosen direction.

But this whole theory falls short when we have to explain the phenomena wherein the involuntary tokens furnished by the principle of the *expressional exterioration* of every state, psychic or organic, no longer come into play. Unless we are ready to extend sensorial perceptivity beyond all reasonable bounds, and to make it as incomprehensible as the phenomenon of transmission itself, we must have recourse to another principle, which shall explain for us, not apparent transmission, but true transmission.

True transmission means that the state *a* of brain A is reproduced by brain B, without the intermediation of signs, whether visual, auditive, olfactive, or tactual.

Of course in practice these two kinds of transmission must commonly be confounded, and only in experiments made expressly for the purpose and at a certain distance can we be sure that true transmission alone is in play.

Though thought is purely a phenomenon of the brain, in the sense that it cannot be produced by any other organ, still it is never restricted to the brain alone as regards the manifestations that accompany it. *There is no thought without expression;* we might even say with Sietshenof that there is no thought without muscular contraction; but I prefer the first formula, which is the more general one, inasmuch as it includes also the secretions, the emanations, the direct production of heat and electricity. One may stand absolutely motionless and think of all manner of things, yet on analyzing our attitude attentively we find:

1. That if we are reflecting with any degree of intensity, there is always an inchoation of speech; the larynx, the tongue, even the maxilla executes slight movements;[1]

2. That if our thinking presents a visual rather than an auditive character, then the eye, though shut, follows the movements of the

[1] I called attention to this fact in my work on Method, "Méthode des Recherches Psychologiques," 1869.

imaginary objects and the pupil is dilated or contracted according to the brightness or the remoteness of those objects;

3. That the respiration is governed, accelerated or slowed, according to the course of our thoughts;[1]

4. That in the muscles of the members there is always an internal contraction answering to the unexecuted movements we think about, or appropriate to the sense-images in our mind;

5. That all emotive states are accompanied by a corresponding change in the circulation;

6. That a concentration of the will is reflected in a corresponding contraction of the diaphragm;

7. That all these phenomena must determine a modification in the functions of the vegetative life, in the exchange of matter, and consequently in the production of the various secretions and emanations;

8. That all psychic work determines a production of heat, and that probably there is a direct transformation of psychic work into radiant heat.

The effect of these actions cannot be restricted to the surface of our body, and, consequently, even at a certain distance, these changes may imperceptibly influence the senses of some other organism and make themselves felt, more or less distinctly, by an exceptionally impressionable organism.

By having regard to but one class of sensations one may reach partial, incomplete explanations. One might, for instance, say:

1. That the subject reads the operator's thought in the visual pathognomic signs, and that therefore the theory of mental suggestion resolves itself into a theory of an exalted visual sense;

2. That as thought is habitually expressed in speech, and as the subject may present an extraordinary hyperacusia (be it said in parenthesis that this hyperacusia never extends more than some yards' distance for words *really* pronounced), we may regard mental suggestion as *an exalted audition* of the inward speech and of the respiration-sounds;

3. That inasmuch as it has been proved that emotions are accompanied by a modification of the cutaneous odor, we may magnify the value of these indicia and hold that every thought that is in any degree concentrated and persistent, especially the thought of approval or of negation (and perception of these two thoughts may greatly assist a subject who seeks to execute an order given him), that each such thought is characterized by a perceptible olfactive modification;

4. That the heat given out because of a mental effort, as modified by the approach of the operator's body and by his gestures (air-

[1] See my work "Bedingungen des Bewusstwerdens." Leipsic, 1874.

currents), may guide the subject, may, in particular, enable him to perceive the inception and the direction of the action, and may thus account, upon grounds purely of caloric action, for influences said to be mental;

5. That in experiments with direct contact all the expressive vibrations and tensions of the muscles may serve as unmistakable pointers to an interpretation of our thoughts: this would be a *mechanical* theory of suggestion;

6. That as the phenomenon of reflex *attraction*, based on an exalted cutaneous sensibility, can be developed very highly so that the subject shall be attracted by gestures that are hardly made at all, one might adopt a purely *attractional* theory of suggestion, and say that all the movements mentally ordered are executed because of a *reflex physical attraction;*

7. That the phenomenon of the *imitation* of movements being a common one and capable of being largely developed, we may suppose that if, even with the eyes closed, the subject can repeat the movements of the operator, the same phenomenon, in a slightly higher degree, might be presented with regard even to incomplete movements; that would be a purely *imitational* theory.

All these considerations taken separately, or even taken together, can apply only to a certain number of facts; but we have to bear them in mind wherever, according to the case emergent, any one or more of the principles stated can fairly be appealed to.

A few controlled experiments alone can decide whether or not they apply in any given case.

In general, as regards experiments made from anear, it appears certain that there is a graduation of the facility with which they may be performed. The scale is about as follows:

1. Experiments made with contact, gestures, and looks;
2. Experiments made with gestures and looks;
3. Experiments made without gestures, with looks;
4. Experiments made without contact, gestures, or looks.

Starting from this last degree, the influence, up to an unknown limit, no longer decreases with the distance. If action can be exerted from the farther end of a room *unbeknown to the subject*, it can be exerted equally well from another room, from another house, and so forth.

The fact that a small distance often makes a noticeable difference, and that a great distance makes no perceptible difference, proves:

1. That *in certain cases* contact, gestures, and looks have their share in the action;

2. That neither this action of theirs nor the action of olfactive sensations suffices to explain certain other cases.

Furthermore, contact is very often indifferent, gestures useless, and looks exert no distinct action; therefore, if these agents have any

action at a distance, it must be a subjective one: to wit, it simply helps the operator to concentrate his thought.

On the side of the operator the conditions have been very little studied. But it is probable:

1. That there are personal differences;

2. That these differences may be due not only to the degree of thought-intensity, but also to the nature of the thought itself, according as it is visual, or auditive, or motorial;

3. That some account has to be taken of a sort of accord, of concordance between the natures of the two intelligences;

4. That excessive will-effort impairs the definiteness of the transmission, without much enhancing its intensity;

5. That strong, persistent, prolonged thinking, or a thought repeated for a longer or shorter time, constitutes a condition in the highest degree favorable;

6. That any distraction that causes the thought to disappear for a moment, or that makes it cease to be isolated, seems eminently unfavorable to the mental action;

7. That, nevertheless, thoughts that are not intense, and even thoughts that are at the moment unconscious, may be transmitted involuntarily;

8. That the muscular efforts that always accompany an exertion of will are more or less indifferent; but that the muscle-expression of the operator may be useful, subjectively, by reason of the habitude that connects thought with these expressional signs.

It follows from these considerations that the operator should insist less upon the "I will it" than upon the content of that willing; and hence it is probable that, properly speaking, it is not the strong will that helps suggestion so much as the clear thinking.

As regards the subject, to find the bearings in this question we may consider one after another the four principal states:

1. In the state of *profound aideia*, transmission is never immediate, but it may sometimes be *latent;*

2. In the state of *nascent monoideism*, it may be immediate and perfect;

3. In the state of *passive polyideism*, it may be either mediate[1] or immediate, but always weaker;

4. In the state of *active polyideism*, the conditions are complex, and they must be considered separately:

a. Transmission may be direct if the subject helps by voluntary self-absorption in a concentration of mind more or less monoideic:

[1] Mediate—with a lapse of time intervening between the mental action and the action of the subject.—*Translator.*

he lends himself to the action, he listens mentally, he seeks, sometimes he finds.

b. It may be indirect, that is, latent, this time also with some concurrence on the part of the subject; this case seems more frequent.

c. Finally, it may, in exceptional instances, be either mediate or immediate, even without the subject's being advised beforehand of the action. Here we touch the question of mental action upon a subject in the waking state, and that calls for some explanations. The somnambulic state of active polyideia differs from the waking state only by two characters, of which one is absolute, the other relative:

1. The absolute, *i. e.*, the constant, necessary difference is quantitative only: waking is a state *more* polyideic than somnambulism. In the latter there is always a narrowing of the psychic field. In the waking state, despite the apparent monoideism which has deceived many psychologists (Bain, Wundt, Morell, Horwicz, *et al.*), our thought is always very complex; we have simultaneously a multitude of contending sensations, and a multitude of recollections that are ever striving to free themselves from the pressure of the dominant ideas (Herbart). In somnambulism their number is much smaller; most of the usual sensations are wanting (anæsthesia); most of our recollections are paralyzed; but what may lead one astray, and what (despite the general narrowing of the psychic field) constitutes a peculiar character of this state is, that the sensations and recollections *belonging to a given idea* may be more numerous in somnambulism than in the waking state; the perception is more detailed, though only with regard to one idea, and the associational reproduction more complete, though always strictly in one direction. Hence it follows that the somnambulic state of polyideia is more favorable to mental suggestion, *if the subject is fore-advised of the action;* but if he is not, then the waking state will have the preference. It is easier to influence unbeknownst a waking subject than one clearly in the state of active somnambulism. In the latter case the subject is *more absorbed* and hence *less accessible.* The normal state is in general less sensitive because of the resistance of a multitude of thoughts that are struggling for life, but it is less concentrated, more *elastic*, more diversified, and hence more accessible. What I meant to express when I said "more elastic," is, that in the normal state our thoughts launch out more freely right and left, without losing the clue that guides them; but I used the term chiefly because of this peculiarity—one that is of interest for us on other accounts—that in fact the normal state is not a state out and out polyideic; it is rather a fluctuating (*mobile*) aggregate of all possible states, with preponderance of polyideia. There are unquestionably moments of monoideism in its every grade, and even intervals strictly monoideic. Only, all these phases are commingled, following one another with inconceivable rapidity. But

that is what makes this state amenable to faint influences, particularly in hypnotizable subjects, whose minds are generally characterized by a constant tendency to monoideism.

2. The second difference between the somnambulic state and the normal is only a relative one, but it is of still greater importance for the matter in hand. It is a relative one in that it does not exist in the *hypnotized:* a *hypnotized* subject is not *in rapport* with any one. It is relative also from another point of view, in that, though in magnetic somnambulism there is *isolation* of the subject, the isolation differs only in degree from that of a normal state in which suggestion can succeed. In fact it never does succeed—at least immediate suggestion does not—in a normal state in which there is *no trace of rapport.* This rapport must be established, either by repeated magnetizations, by a tie of blood, of sympathy, of daily association, or by some exceptional influence of the moment.

This detail brings us to the very heart of the subject. Rapport being a *conditio sine qua non* of distinct mind action, let us strive to define what it is.

As we have already observed in the opening of this study, and then in remarking upon Despine's experiments, the nature of this phenomenon is essentially two-fold—psychic and physical. We already know the psychic elements, which are the predominant ones in regard of the frequency of their plain manifestation, but we have now to analyze the *physical cause* of the phenomena of rapport.

"There's the rub!" Are we justified in asserting that "animal magnetism" has a physical cause?

Observe in passing that, considering the general aspect of the phenomena hitherto lumped together under the one denomination of "hypnotic" phenomena, this cause is not necessary save for certain classes of facts; the rest can do without it. But that does not remove the difficulty: it remains, though in shadow. And what shocks the "regulars" is, that this physical action "upsets every notion of physiology."

"I never could understand," says Mr. Brown-Séquard, "how an intelligent man, acquainted with the ground principles of physiology, can believe in such transmission (a transmission of nerve-force from one individual to another), seeing that the student who has learned ever so little knows how vain, after a motor nerve has been severed, is the effort, the wish, the will to move the paralyzed part"[1]

I should not like to pass for the most uninstructed student, still less should I care to set up as teacher of my honored master, to whom I am indebted for more than one excellent idea, but—*amicus Plato, magis amica veritas*—I venture to say that even I see how the paralyzed part might be moved.

[1] Preface to Simon's French translation of Braid's "Neurypnology."

The will, says Mr. Brown-Séquard, cannot reach a muscle the motor nerve of which is severed, whereas it seems to him quite natural that it should be able to reach a muscle whose motor nerve is not severed. Now to me that does not seem natural at all. I agree that it cannot reach a muscle whose motor nerve is severed, but at the same time I do not believe that it can reach a muscle whose motor nerve remains intact. The will is a cerebral phenomenon, that never has been found (*constaté*) outside of the brain, and that cannot outstep the brain. It is not even transmitted to the motor nerve that issues from the brain and terminates in a muscle. So, too, the mechanical motion of a muscle is not transmitted to the sensor nerve to reach the brain, but it may, it necessarily must, give rise to a molecular current; that current is transmitted to the brain, and therein calls out another dynamic phenomenon the nature of which is unknown, but which we distinguish quite clearly as *sensation* or *idea*. It is the same with the will. To reach a muscle, the will absolutely requires a molecular intermediary which shall traverse the nerve, and it is entirely true that this intermediary cannot leap over where the nerve is cut in two. Neither can a telephonic current, though less capricious, overleap a break in a wire: the telephone will be dumb. And were we to stand still at this experiment we should be fully justified in saying of the telephone what Mr. Brown-Séquard says of the muscle.

Fortunately, our science does not stand still there. Mr. Brown-Séquard, in proclaiming two indisputable truths, makes two mistakes. The two truths are these:

1. Nerve-force cannot traverse a severed nerve;

2. *Nerve*-force cannot *pass* into another nervous system.

Very true; nor do I believe in any passage of any nerve-fluid.

But does that mean that nerve-force, or any force whatsoever, acts only where it is, and that its action is absolutely restricted within the body in which it manifests itself visibly?

Here the error begins. It is twofold, for—

1. Such force, thus absolutely limited to any material point whatever, does not exist;

2. If it did exist, the most fundamental principles of physiology, among them Mr. Brown-Séquard's principles of inhibition and of dynamogeny, would be upset.

The normal action of a telephone ceases when the wire is broken. It is equally null for us when, though the wire is not broken, the circuit contains only one telephone. Is it possible to transmit speech with one telephone? No; and yet the telephone works. The whole length of the wire is traversed by a current which is not speech itself, but which is its correlative, though it is dumb.

Take another telephone having also a closed circuit, and, like the first, dumb. Bring it near the other, or only near the wire of the

first telephone, or even simply bring the wire of the first near the wire of the second, and *the latter will talk*, will reproduce speech, though there is no material contact between the two. It will talk by *induction*. It is this transmission, not that which takes place between muscle and brain, that corresponds to mental transmission. *My brain does not act upon the muscles of the subject, but it may act upon his brain.* If instead of a second telephone we were to place alongside of the first telephone a different sort of instrument, an electroscope, for example, there would be no result; but we must not by any means infer that therefore there is no electric action all around the telephone, for in order to get a specific action we must employ a specific instrument, a telephone for a telephone, a brain for a brain.

I do not at all mean to strain the analogy; comparison is not proof; and were there not other evidences of inductive physical action this would be of no avail. But the case is not so. Apart from all theory, facts compel us to admit a physical action: we should have to admit it even were there no other analogous phenomenon.

Here are the facts in brief. Of course I cannot here prove their reality, but shall merely mention them, believe them who will:

1. Sometimes the magnetized subject discerns the presence of his magnetizer independently of the ordinary sensations. His touch he distinguishes from that of others—distinguishes it even though it be applied by means of an inert body (a rod, for instance), which of itself cannot influence him differently. If, therefore, the subject distinguishes his magnetizer's touch as well through a rod as directly, it must be that there exists a molecular current of some sort peculiar to the organism of the magnetizer, and which indicates his presence in much the same way that a galvanic current, through the intermediation of a wire in contact with us, indicates the presence of a pile. The objection that most subjects feel nothing of this action is of no weight, for so, too, with a current from a weak galvanic element we shall feel nothing, while the magnetic needle will clearly prove its presence, and with a current weaker still, from a telephone or from a frog, the magnetic needle will show no result whatever: an exceptionally sensitive galvanometer would be necessary in such a case. Suppose that 40 years ago, when Mr. Du Bois-Reymond published his discoveries in electricity, some one had challenged his assertions, saying that no galvanometer had shown the presence of the currents he declared to exist: the assertion would have been true, but nevertheless unjust, for at that time Du Bois-Reymond *alone* possessed a *multiplier* capable of showing their presence.

2. We can obtain marked results of a therapeutic kind by acting without contact and unbeknown to the patients operated upon, sleeping children, for example. Hence, there is an inductive action that overpasses the superficies of the body.

3. We find marked differences in the so-called magnetic action of different persons—differences not to be explained by moral action. One hand acts differently from another hand. Hence, there is a physical action, and a *personal* physical action.

4. Finally, inasmuch as facts compel us to accept action from afar, we must needs admit real[1] action from anear.

Though we cannot define with precision the nature of this action, we can nevertheless affirm that:

1. Every living being is a dynamic focus;

2. A dynamic focus tends ever to propagate the motion that is proper to it;

3. Propagated motion becomes transformed according to the medium it traverses.

Let us enter a little into details.

Whether forces, as such, exist in nature, I know not; *a fortiori* I do not know whether they exist outside of nature; what I do know is, that so far as it is knowable, force is nothing but motion. We say "motion," when we see motion; we say "force," when the motion is invisible. A sleeping animal possesses the "force" to rise, for there exists in it a latent, hidden molecular motion that may be transformed into visible mechanical motion. When the animal is dead it possesses this force no longer, for the inner molecular motion constituting the biological exchange of matter is no more. Hence, we may regard this force as molecular motion.

Motion tends always to propagate itself.

Why does it seem sometimes to disappear? Can it annul itself? No; as motion is not self-produced, so it is not self-destroyed. Therefore, when we see work of any kind—mechanical, electrical, nervic or psychic—disappear without visible effect, then of two things one, either

1. A transmission; or

2. A transformation.

In a medium that opposed no resistance, a motion would be transmitted indefinitely. Imagine a universe consisting of a medium motionless, but capable of being set in motion, and presenting no resistance, and to set that whole universe in motion, we should need only to give an impulse to one single atom. And were that atom alone, it would move on for all eternity. It would proceed in a right line, according to the old law of mechanics, but in an infinite circle according to the new—and that is the beginning of the scientific farces.[2] Suffice it to say that there would then be no reason why the motion should cease.

But the universe is not like that; there is resistance. What is

[1] *Réelle*, physical, opposed to *moral*, in par. 3.—*Translator.*

[2] *C'est ici que commencent les farces scientifiques.*

the meaning of this resistance? To explain it we have done as savages do—have endowed matter with the qualities that belong to ourselves. After having "objectivated" a subjective muscular feeling in the notion of "force," we proceeded to do the same for that which "opposes" force, giving to matter our own "inertia," our own indolence. Inertia has no existence any more than force, any more than absolute rest. But what does surely exist is *motion, which opposes another motion, if it is not of the same nature.*

What happens then? The initial motion is *transformed.*

Such is the great principle of the universe; not merely "transmission," as Puységur held, but *transformation.*

Where does the first end and where does the second begin? Physical philosophy gives us a very clear idea with regard to that point:

a. In an identical medium there is only transmission;

b. In a different medium there is transformation.

A dynamic nucleus, in propagating its motion, sends it out in every direction; but this transmission becomes perceptible only *on the lines of least resistance.* Hence we say that magnetism chooses iron; that heat, like sound, chooses good conductors; that a galvanic current gives the preference to a thick wire among many fine wires, as lightning chooses the line of its route, as a light-impression chooses the nerve that suits it, as the will chooses the fiber that serves its purpose; and so on.

But in reality nothing chooses anything. We it is that do this choosing, subjectively, owing to our inability to see invisible things. The pressure exerted by a liquid confined in a vessel is the same when its wall is intact as when a hole is pierced in it. But the liquid does not escape save when the wall is pierced, and then the other pressure concerns us little. Instead of a substance let us take a force. Cast a stone into a lake not far from the shore. The shock will produce a series of waves. These are visible on the surface of the water. Do they end at the shore? No! The land receives the shock like the water, and propagates it; only, it propagates it in its own way, invisibly. What does a force do that strikes a medium unsuitable to its kind of motion? It becomes transformed, that is all. It is so always, and there are no other causes of transformation. Transformation implies resistance. You send an electric current through a thick wire. You have the current, but you do not perceive any other force. But cut that thick wire and connect the ends by means of a fine wire: the fine wire will grow hot; there will be a transformation of a part of the current into *heat.* Carry the experiment further. Take a pretty strong current and interpose a wire still more resistent, or a very thin carbon rod. The carbon will emit *light,* and the light will be still more intense if you cut the carbon in two, introducing a conductor still more resistent—air. A part of the

current then is transformed into heat and light. Think you that this light acts only as light, and only in the lamp? Not so! It acts in every direction round about, first visibly as light, then invisibly as heat and as electric current. Hold a magnet near it. If the magnet is weak and movable, in the form of a magnetic needle, the beam of light will cause it to deviate; if it is strong and immovable, it will in turn cause the beam of light to deviate. The rays of light that impinge on the non-transparent vanes of a Crookes radiometer make the mill go round. And all this from a distance, without contact, without special conductors. And all this[1] because, somewhere far away, somebody turns a crank, or because an almost imperceptible chemical process is going on in a battery!

A process that is at once chemical, physical and psychical, goes on in a brain. A complex action of this kind is propagated through the gray matter, as waves are propagated in water. These phenomena are intense in a different way: their intensity is not mechanical, it is more subtile and more concentrated. What we call an idea is a strictly localized phenomenon. But we must not forget that to produce an idea, thousands of repeated impressions were necessary, and every one represents a force. That force is accumulated, condensed, as it were, in an idea. Regarded on its physiological side, an idea is only a vibration, a vibration that is propagated, yet which does not pass out of the medium in which it can exist as such. It is propagated as far as other like vibrations allow. It is propagated more widely if it assumes the character which subjectively we call *emotive*. An emotion is more expansive than an indifferent idea: it may occupy the whole brain to the disadvantage of all other ideas. But it cannot go beyond without being transformed. Nevertheless, like force in general, it cannot remain in isolation, it escapes in disguise. The official world of science allows it only one route—through the motor nerves. These are the openings in a dark lantern through which the luminous rays pass. But thought does not radiate like a flame, nor even like the heat of a flame, though that makes little account of the opaque walls that are impermeable to light.

Thought stays at home, as the chemical action of a battery remains in the battery; it is represented abroad by its dynamic correlate, called, in the case of the battery, a current, and in the case of the brain—I know not what: but whatever its name may be, it is the *dynamic correlate* of thought. This dynamic correlate is not, nor can be, restricted to the nervic currents of the motor fibers. It represents *all* the transformations of cerebral motion—transformations all the more subtile and all the more radical, as the difference is greater between the anatomic medium of thought and the environing

[1] The electrical and magnetic phenomena mentioned, *not* the revolution of the Light-mill.—*Translator*.

media: bodies solid, liquid, or gaseous, with the ether considered as the fourth state of matter and, relatively, filling the universe.

Let us halt for a moment. We have reached the conclusion that the motion that answers to thought cannot be exceptional in nature, and that like all force it is transformed into other forms of motion, logically necessary though for the most part unknown.

"No displacement of matter," says Mr. de Parville, "takes place in inanimate nature, no act, voluntary or unconscious, takes place in living nature, but that there is a production of electricity in exact ratio to the energy of the work expended."[1] Besides electricity, there is production of heat, production of mechanical motion, and, perhaps, production of light. But I do not intend to go into particulars. I believe we do not know one thousandth part of the molecular changes that a thought may produce, and we must content ourselves with simply noting the facts: here, as elsewhere, energy is transmitted and transformed.

CHAPTER VIII.

THE LAW OF REVERSIBILITY.

SO then we must regard thought as a dynamic act. That dynamic act is developed at the center of a larger dynamic focus which is called nerve-action; and the latter must be considered as a special mechanic action resting on a basis wider still—the whole vital aggregate. The entire organism has a dynamic *tone* peculiar to itself and dependent on the individual's general anatomical and physiological nature, as well as on his state of equilibrium at the moment. This equilibrium is governed by the nerve-tension, and the latter by the individual's psychic mobility. This triple dynamic microcosm acts upon a medium, first by its presence only, as a living mechanism, next by its state, as a nerve-system, finally by its thought, as a psychic center.

Motion being contagious, we can see that a *tone* that is sufficiently pronounced may be communicated to surrounding objects, and especially to another organism whose individual tone is less masterful, and which is distinguished by passive mobility and readiness to be modified. The influence no doubt is reciprocal, but it is the

[1] H. de Parville, "L'Électricité et ses Applications," p. 17. Paris, 1882.

stronger, the more largely constant, the more invasive modality that gives the tone. And then an extrane contact will produce either a dissonance unpleasant to the subject, or no effect at all, according to the firmness (*solidité*) of the dominant tone. When the effect is *nil*, we have to do with a strong, decisive current that withstands all interruption. The more the dynamic union is insured by contact, by repeated passes, by the physiological submission of the subject, the less is transmission balked and the less resistance it meets. Some kinds of motion—heat, electricity—can be communicated without perceptible modification; others are transformed.

But neither the principle of communication nor that of transformation would be of much use in explaining mental suggestion, were they not complemented by another principle which may be stated in a general law of physics.

This we call the *law of reversibility*.[1]

We already know that all motion propagates itself (law of transmission); that all propagated force, when it meets resistance, is transformed (law of transformation); but we do not know what comes to pass on a second or a third transformation. Now it may happen that a motion twice transformed *shall regain its original character*. Under what circumstances might that happen? It might happen if the communicated motion were to find a medium *of the same kind as at its starting-point*. Such is the law of reversibility.

According to that principle a transformation is *always* reversible.

The thing seems, in theory, quite natural, but we must not forget that it is less evident in practice, for but rarely do the same conditions accompany a reiterated transformation. Electricity was for a long time produced by friction without ever a thought that friction, in turn, can be produced by electricity. The phonautograph, *i. e.*, the mechanical action of speech, was long known before men suspected that a mechanical action, in turn, may reproduce speech in Edison's phonograph.

Years ago it was known that under the influence of electricity the conductivity of glass as regards light may be changed; but it is not long since it was found that, inversely, light can alter the electric conductivity of selenium.

Hence may be seen the utility of a law which assures us in advance that *if the effect A can be produced by the cause B, then, inversely, the effect B can be produced by the cause A*.

If mechanical work produces heat, inversely heat can produce mechanical work. Savages turned the first of these facts to account, the second was never seriously applied till the invention of the steam-engine.

If electricity in motion can produce a magnet, a magnet in motion

[1] See my essay, "Force as Motion" (in Polish). Warsaw, 1879.

can produce an electric current; and if we obtain a current by mechanical rotation, so, inversely, a current can produce mechanical rotation.

If a chemical action can develop light, light, in turn, can develop chemical action; and if this chemical action encounters certain special conditions, it will reproduce for us an image that was visible before chemical action, and which after chemical action becomes visible again in a photograph.

The magic of science does not cease there. Do you want, by the help of an ordinary lamp, to light another lamp miles away? To do so, you have only to set up a series of transmissions. You use your lamp to heat a Clamond thermelectric battery. The difference of temperature between two metals gives you a current. This current, you, being in Paris, send, say, to Versailles. There you oppose resistance to it by means of a very slender platinum wire. The platinum wire grows hot, and on touching the wick of a lamp, lights it.

But you needed to have a special *conductor* reaching from Paris to Versailles. You must have a conductor also to produce a reversed transformation of mechanical motion in a dynamo connected with an electric motor. One is needed also for reversed telephonic transmission. But a more surprising thing is, that there is a way of reproducing speech at a distance *without conducting wires.*

You substitute for the wire a ray of light.

Here is the principle of the photophone: A ray of light is reflected by a very thin mirror and projected to a distant point. Back of the mirror is fixed a mouthpiece. By speaking into the mouthpiece you cause the mirror to vibrate. A vibrating mirror modifies the reflection of light. The light that reaches the other station is modified by your speech, has your speech to carry, not as speech, but as represented in its mechanical correlate. It reaches the station and impinges on a lamina of selenium. The selenium is traversed by a local current. But the lamina of selenium offers to this current a resistance greater or less in proportion to the brightness of the ray that impinges upon it. This constantly modified current you pass into a telephone; it causes the disk of the telephone to vibrate according to the modifications it undergoes—and it reproduces your speech.

Is it possible that a ray of light may transmit speech? Most assuredly, for the thing has been done by Bell and Tainter. But what physicist 20 years ago would have admitted it?

Let us note what takes place when this experiment is performed. Your brain gives your thought, transformed, to the nerves; the nerves transmit it to the muscles and the vocal chords, they to the atmosphere, the atmosphere to the mirror, the mirror to the beam of light, *i. e.*, to the ether, the ether to the selenium, the selenium to the battery current, the current to the electro-magnet of the telephone,

the electro-magnet to the vibratory disk, the disk to the air, the air to the tympanic membrane, the tympanic membrane to the ossicles of the middle ear, these to the membrane of the labyrinth, that membrane to the liquid of the inner ear, that to the terminal organs of the auditory nerve; and, finally, that nerve conveys it to the brain. And that brain reproduces the thought of another brain. Why? Because the latest transmission has found a medium of the same kind as at its starting-point.

Think you that this was never done before Bell and Tainter's time? Why not? Everybody that ever spoke before a mirror—and, in a certain sense, everything is a mirror—sent his speech out into the whole world. And let us not forget that this is but one application of a general law. Everything is transmitted, everything is transformed, everything may be reproduced.

If anything is not reproduced visibly, palpably, the reason is that the conditions of reproduction are more or less remote from perfect likeness between the media. Find you a receiver that is sufficiently sensitive and you will have reproduction. In vain have you a telephone unless there is another telephone to act as receiver. But the telephone is but a coarse type of a biological reversed transmission. The photophone is a more delicate instrument: it does without wires; a ray of light serves its purpose. Some day we shall dispense with that one reflected ray, and will employ any intermediary whatever, a jet of water, a current of air. Inventions are ever advancing from the complex to the simple as regards fundamental principles, though in the details there may be greater complexity.

But observe what results from this experiment, to wit, among other things this, that light may be made a vehicle of speech. Well, in like manner the warmth of the hand may be made a vehicle of health or of a good intention.

The cry will be raised, *Mysticism!* So much worse for those that raise it: they will miss the opportunity for learning a grand truth! It matters little to me that the truth has been propagated by an ignorant crowd; forasmuch as it is truth let us give thanks to the crowd. Yes, as the *la* of a musical instrument is not the *la* of the vocal chord of a man or a woman, of an individuality, so the warmth of a hand is not the warmth of a poultice. Do not call in the thermometer to decide! A thermometer has no business to be the arbiter of such a difference, any more than a barometer has to judge the purity of the atmosphere, or a pair of scales to judge the quality of two wines. Let us be less boastful of our science, so our science may be more boastful of us. If everything could be learned in school, what, I ask myself, would be the use of the science that investigates?

One remark more. While availing ourselves of the law of transfor-

mation, we must not forget that the transformation is never total. I say *never*, and I mean it. In another place I have endeavored to prove that a force A is always transformed into more than a force B, C, D, etc. A blow with a hammer produces not only a mechanical concussion, but also heat, electricity, a sound, a magnetic change, sometimes a spark, and so on. Never is a force A transformed in its entirety into a force B. That is why the mechanical equivalent of heat cannot, in practice, be an absolutely constant quantity, and therefore it is that, instead of the word equivalent, I have chosen rather to use the term *dynamic correlate*. There is something more than that: the universe is neither void nor dead. A force that is transmitted meets other forces, and if it is transformed only little by little, it usually limits itself to *modifying* another force at its own cost, though without suffering perceptibly thereby. This is the case particularly with forces that are persistent, concentrated, well seconded by their medium: it is the case with the physiological equilibrium, nervic force, psychic force, ideas, emotions, tendencies. These modify environing forces without themselves disappearing; they are but imperceptibly transformed, and if the next man is of a nature exceptionally well adapted to them, they even *gain* in inductive action, as the magnet gains by contact with an armature of soft iron, to which, nevertheless, it communicates its force. A sentiment that is communicated loses nothing; on the contrary, a polar induction oftentimes strengthens it.

We should have to write a whole psychology and a whole philosophy of nature to elucidate sufficiently these subtile questions. Let it suffice to say that in "dead" nature there are found like phenomena. A spark produces a conflagration, but neither the conflagration itself nor even the first flicker is to be regarded as the mechanical equivalent of the spark. The latter does but *set free a series of latent forces*. If the magnetic telephone of itself produces the current which transmits speech, the same is not true of a microphonic transmitter. The latter requires a battery, and speech only modifies an existing current, impresses modifications upon it, charges it with a mission, without being thereby weakened. It is so with the magnetizer's thought.

CHAPTER IX.

FINAL SUPPOSITIONS.

LET us now betake ourselves to another station and observe what passes there. Let us take the case of sleep produced from a distance and strive to explain it.

Magnetizers tell us that their will concentrates the fluid and then projects it outward, approximately in a given direction, like a package of opium. So intelligent is this fluid, so complaisant, that it hies away with all speed, finds its road, goes round obstructions, and hits the subject. It enters the subject, and the moment it has duly *saturated* him sleep appears, brought on by action from afar or anear. All very clear, and in fact rather more rational than the old-time explanation of the action of opium, according to which the drug endorms one because of its *somniferous power*.

But in the first place the existence of the fluid needs to be proved; then that it can be shot forth, and that it can find its way; finally, that it will stop just when it has entered the nervous system of the subject; in short, the theory is not of much help to us. It describes the action by *substantializing* it, as Mesmer used to say.

Let us look at the matter from another side. Suppose for a moment the suggestional theory alone to be true, *i. e.*, that if the subject is put to sleep, he endorms himself by the act of his own imagination, by ideoplasty. The thought of sleep presents itself to his mind, finds a monoideic moment, and is realized. In that case it is enough that the imperative *thought* of sleeping be transmitted to the subject to cause him to sleep. This thought cannot come to him as a thought. Thoughts do not travel abroad, but we already know that thoughts send forth in every direction their dynamic correlate. There is no substance carried hither or thither, but a wave is propagated and modified more and more according to the different natures and the different resistances of the media it traverses. It may impinge on all manner of bodies without any *sensible* action; and I say *sensible* (that is perceptible by the senses) because it were contrary to the mechanical ground-principle of the universe to say that it has *no* action. (True, we are guilty every day of such inexactitudes. We say, for example, that the moon causes the flux and reflux of the ocean, but that it has no action upon the atmosphere or upon man.) The action, therefore, is general, but it is more or less imperceptible till the undulation finds a medium like the original one, and all the conditions requisite for a reversed

transformation. A brain B presents these conditions; in it the corresponding thought awakes, and brain B falls asleep.

"But then all the sensitive brains within the sphere of the action must be endormed also?"

Not so, for all those brains are not *regulated*, are not in rapport with the operator. I do not think it possible to act at a distance without rapport. And rapport consists in this, that the dynamic tone of the subject corresponds to that of the operator; that, through habit and training, the subject's brain has become quite specially sensitive to the slightest influences of the magnetizer.

Allowing that mental action from a distance is a fact, is it conscious or is it unconscious? That is to say, has the subject any intimation of it before he submits to it entirely?

Usually he has not. The transmission is mediate—from the conscious to the unconscious. The thought suggested does not enter into the normal polyideia; but, having found a moment of monoideia —a moment of *absolute* monoideia is never a moment of consciousness: who says *consciousness* says *polyideia* — it is realized forthwith by ideoplasty. It is, then, only in the somnambulic state that the subject can perceive the process of the influence and divine its cause. Often in such case the image of the operator is suggested at the same time, producing a veridical hallucination.

But it also happens that the subject divines the action before he submits completely to it. Sometimes even, particularly when the operator falters for a moment, the subject gets time to make resistance. In that case we have to do with an immediate suggestion that is insufficient either because of the operator or of the subject. But then, as a rule, the balked immediate suggestion is transformed into a mediate, a retarded suggestion, and that may later find its favorable moment.

The action may, therefore, be conscious or unconscious; but is it always purely cerebral? In other words, is transmission effected in the subject through the brain acting on the organism, or through the organism acting upon the brain?

According to Baragnon's hypothesis, that the transmission of sensations is the foundation of all mental suggestion, the nerves, they being affected first, re-act upon the brain.

Viewed from the ground of general physiology, this hypothesis is not without foundation. The law of reversibility applies no less to the physiology of the nervous system than to physics. If an emotion finds expression in a muscular attitude, that muscular attitude, when impressed upon a subject from without, may conversely produce an emotion. This is proved by Braid's *muscular suggestions*. So, too, transmitted sensations might reproduce the thoughts that accompanied them in the mind of the operator. But, in the first place, has

the operator actually in his mind the sensations of sleep when he produces sleep? To say that he has would be to do some violence to the facts. He has only the *idea* of sleep; and then I think that, at least as regards experiments made at a distance, the sympathic action of two brains is more easily conceivable than the sympathic action of nerves; and, since the brain itself suffices to produce, by centrifugal action, all possible sensations, it is best to regard the brain as the direct recipient of the mental action.

Hence I hold, or rather suppose, that an action at a distance may be exerted solely, or principally, through the intermediation of the brain.

True, we have admitted a physical action; nay, a local physical action. But it is almost impossible in hypnology in general to eliminate the co-operation of the brain, that is, of ideoplasty or of sensorial reflex action. You may, indeed, act upon one member separately; you may paralyze a single finger, or a single ear; but we must not be led astray by an apparent local action produced by passes, or by the hand, a magnet, metals, or sundry medicinal substances when brought near to the subject: even when the brain seems to be in deep sleep it may re-act through reversed ideorganic associations. Only one kind of local physical action seems to be admissible—the kind analogous to the communication of heat. I can warm a cold hand by holding it between my own warm hands, and then the action is not reflex, but purely physical. Probably there are other physical transmissions of the same sort. It is probable that a hand well supplied with blood, well fed by the normal currents of the muscles and nerves, a hand that transpires in the normal way, that, in short, is perfectly equilibrated in the sum of its molecular vibrations—it is theoretically probable, and true in fact, that such a hand can communicate its *tone* to a diseased part; can, by induction, revive a slowed molecular motion or a languid physiological exchange of matter; can stay dynamic excess of the vital processes, and can restore equilibrium when it is disturbed.

I can understand how all this may be done, even at a little distance, if the hand be directed toward the part affected. But I cannot well see how similar action can be performed from a great distance or from the opposite side of a wall; and I think that in such case there is no longer direct physical communication, but rather cerebral suggestion; and if Mesmer's subject (p. 260 *supra*) sensed at the other side of a wall the movements of the magnetizer's arms, he perhaps did so in virtue of a transformed and reversed thought-transmission and of mentally suggested ideoplasty, rather than of local physical action. But we will not dwell upon this question, for as yet it is not susceptible of thorough discussion. Nevertheless here are some inferences that I think may be drawn from several

of my experiments as well as from the experiments of Bertrand and other authors.

Contrary to what we should expect according to the theory of the exaltation of the senses, mental suggestion seems to be most successful when the senses are paralyzed. Then, too, we are certainly in presence of true thought-transmission. There is an *exaltation of the brain*—a quite special exaltation that we shall presently endeavor to make clear ; but there is no exaltation of the senses.

The question here mooted is full of difficulty, and I present my hypotheses concerning it with all reserve.

Mesmer, it seems to me, was once again right in regard to this. He held that the subject whose senses are *absolutely* paralyzed (as happens now and then in catalepsy and in ectasy), nevertheless hears his magnetizer, *hears him by mental suggestion.*[1] Speech, though uttered *viva voce*, directly impresses his brain, not his ear. It might happen that thought without speech would be insufficient to influence the subject, but even so the hypothesis would stand, for the transmission might be too weak unless aided by speech.

Mesmer was partly in error : he made too wide a generalization. He believed that *in all cases* whenever the subject hears only his magnetizer, he hears him mentally. But as we have seen, the phenomenon of rapport can in some measure be explained by a *specific* impressionability, by an *elective* perception, and we must always recur to influences that are known before we have recourse to an essentially new hypothesis. And yet, if instead of a relative anæsthesia we find absolute and general insensibility, so that a pistol fired suddenly alongside the ear of the subject produces no impression, no reflex motion, it is difficult indeed to understand how a word from the magnetizer, spoken also unexpectedly, and even with a change of voice, is heard perfectly well.

It is probable, then, that there are two kinds of mental suggestion : one conditioned on an exaltation of the senses—an exaltation with respect to sensations coming from the part of the magnetizer, constituting rapport ; and another conditioned on complete paralysis of the senses, with a quite exceptional exaltation of the brain.

In the latter case there is always a sort of fever localized in the brain alone. The head is hot. One would say that all the nerve force is concentrated in the hemispheres. There is hyperæmia, but hyperæmia of a special sort—hyperæmia *from electric tension*, one might call it ; it does not oppress the brain, it only gives it an excess of available, but latent vitality. The circulation is not rapid, but it may at any moment become more rapid than usual under the influence of the slightest excitation.

[1] Puységur, it will be remembered, mentions the case of a deaf patient who made answer to mental questions.

If it is the action of the vaso-constrictors that regulates the capillary circulation, then in this case we must concede to them an extraordinary mobility of excitation and relaxation. As for the electrical phenomena, they might be explained as follows: The classic researches of Du Bois-Reymond have shown that the currents proper to the nerves as well as to the muscles undergo a reduction of tension (*affaiblissement*) during nerve-action proper; that is, that a given quantity of energy manifests itself, now under the form of nerve-action, anon under the form of electric action. In the case we are considering the psychic nerve-action is null; but it may become very intense. Consequently, there must exist in the brain an exceptional electric tension, which, however, may disappear rapidly, and which in general is subject to great momentary changes. When the brain is in aideia the electric tension is high, and it excites the vasomotors, which contract the arteries. But because of the relative hyperæmia and the consequent tension of the blood, particularly of the arterial blood, the slightest reduction of the electric tension may increase the work of the nerves and cause a dilatation of the arteries. Hence we need only suppose that the electric currents of the atmosphere, modified by a psycho-physical transmission (as in the case of the photophone the ray of light is modified by speech), transmit that modification to the electric currents of the brain, which is, by the sum of these conditions, made amenable to the slightest influences, in order to understand the reproduction of a mental phenomenon transformed into its dynamic correlate.

I beg the reader not to be over-critical of this little excursion into the region of the invisible. It may be that things are quite otherwise; in particular it may be that this inward process is far more complex than it would seem to be from my conjectural sketch. One does the best one can so as not to seem awkward in the presence of a phenomenon that "upsets all the notions of physiology." Let us hope that, after all, it will not upset anything, and that it will shed a clear light upon many an obscure fact.[1]

To that end, we have to show that the phenomenon is closely connected with other phenomena that are near at hand and more or less known. If the law of reversibility explains action at a distance, it must also explain action from anear, and that should have its analogues in facts still more rudimentary.

As we have already remarked, mental action at a distance is

[1] On the question of the state of the brain in natural sleep, see the excellent work of Dr. A. M. Langlois: "Contributions à l'Étude du Sommeil Naturel et Artificiel," Dijon, 1877; an interesting essay by Dr. H. Haan: "Ueber die Beziehungen zwischen Hypnotismus und Cerebraler Blutfüllung," Wiesbaden, 1885; and a recent descriptive work, full of quotations, by Dr. Barth: "Du Sommeil Non-naturel." Paris, 1886.

closely associated with physical action from anear and with several phenomena of sympathism and of nervic contagion. Let us now descend still lower, to the very bottom of the scale, in order to discover the connection between the two series of phenomena.

Action at a distance exists within the individual organism. "It is," says Maudsley, "a characteristic property of the nervous system, that a local excitation is immediately transmitted to distant parts. How is this done? We know not. We may therefore designate the phenomenon either as sympathy or *consensus* of parts, induction, infection, or reflex action, or by any other name that, like an algebraic symbol, may express an unknown quantity." "How are we to account for the fact," says Mr. D. Whyte, "that sometimes the amputation of an arm or a leg produces contraction of the muscles of the jaw, rather than of any other organ?" Our ignorance thereanent need not surprise us; nobody knows why, in a sensitive plant, *Mimosa pudica* for example, excitation applied at one point is propagated throughout a whole leaf, and sometimes even to the neighboring leaves, which contract; in fact no one knows how electric induction is produced, nor why a single point of an excited muscle transmits the excitation through the entire length of the fibers, nor how the substance of a nerve is transformed in the electro-tonic state.

But in order to understand the principle there is no need to know all this in detail. The principle is manifestly contained in the laws we have just pointed out.

Any excitation caused by an anatomical or a purely dynamical change, whether spontaneous or induced, always constitutes a center of motion. This motion, like all motions in nature, is propagated. If it is propagated through an identical medium (nerve-fibers of the same kind), there is only transmission. If it enters a different medium there is transformation; and then it is that there is manifested, in the same individual, the phenomenon of sympathism.

An inflammatory state of the pituitary gland may be transmitted to the mucous membrane of the eyelids, larynx, lungs, intestines, anus, etc., in whole or in part, and then there is only transmission. But it may take place athwart the intermediate mucous membranes *without affecting them*, and then attack a remote point that individually constitutes a *nodus minoris resistentiæ*, for here, as elsewhere, the transmission becomes evident only along the routes of less resistance.

There will be complete transformation if two *different* organs react upon each other from a distance. Thus a displacement of the uterus may bring on an attack of melancholia, which disappears when the organ is restored to its place (Schröder van der Kolk); if the action goes to the brain, the reason is that the brain was specially

predisposed. I have noticed another sympathism of this sort. In an ataxic patient a displacement of the uterus produced sciatic pains that ceased directly after the organ was put in place. In this instance the sciatic nerves presented a favorable field (on account of the ataxy), while the brain resisted all influence. I have also seen dorsal anæsthesia transformed into nervous hepatic colic. The malady changed its place as well as its character from one day to the next, and I obtained a rapid cure by a series of those "transfers."

The state of pregnancy not infrequently produces mental alienation, but again it may restore sanity, so that a patient will be sane only during that period (Guislain, Griesinger). A pessary will instantly suppress melancholia in certain cases (Fleming, Maudsley), just as pressure on the ovaries may arrest an hysterical attack (Charcot), and in the male pressure on a testicle may arrest an attack of hysterical epilepsy (Abbe). It is known that the presence of worms in the intestine may cause nasal pruritus and other sympathic phenomena, and that a needle in the same region may produce convulsions.

But of special interest is total transmission with total transformation, seen in many complaints, and which has been observed by Dr. Darwin, and lately by Maudsley. There is a certain antagonism between *convulsions* and *delirium*. Very often delirium makes its appearance the moment the convulsions cease, and conversely. In such case the excitation of the spinal cord is transferred to the brain, and there is transformed under the influence of the medium.

On the other hand, when transmission takes place in a transverse direction, *i. e.*, from one side of the body to the other, it usually meets an homologous organ, and therefore does not change in character. Thus a headache, any neuralgia, a contraction or a contracture, an anæsthesia or a hyperæsthesia, passes from right to left, and the phenomenon of hypnotic "transfer" shows that *all* unilateral phenomena, sensations and hallucinations (Féré) may be transferred.

This phenomenon is well known in its essential features from the report of the commission appointed by the Biological Society (of Paris) to investigate Dr. Burq's metallotherapy. But sometimes the "transfer" presents peculiar characters. Here, for example, is an interesting fact observed by Ollivier: In a case of left hemianæsthesia, by puncturing the numb leg, that author produced a sense of pain at the corresponding point in the opposite one. I observed a similar fact in the case of a healthy young man, one of my pupils in the University of Lemberg. I could produce in B. a clearly localized anæsthesia in the waking state. I would draw on his forearm, *e. g.*, a square or a triangle, and with my finger would give the spot a slight massage; after a couple of minutes the square or the triangle of skin would be numb, but *sometimes* I could, by puncturing the arm,

produce in precisely the corresponding part of the other arm the painful sensation of pricking.

There exist therefore in the same organism:

a. An action at a distance (excitation reflected in a remote organ). Note that the excitation may be of psychic origin, and that all cases of *trophic* or *material ideoplasty* may be regarded as phenomena of mental action at a distance within the same organism;[1]

b. A transmission with partial transformation apparently entire (transmission and transformation of the disease of one organ to another different one). Here, too, the starting point may be psychic;[2]

c. A transfer of symptoms (that is, a reversed psychical or physical transmission to analogous bilateral organs).

Rising a step higher, we observe a transmission from one organism to another that is connected with it only by community of nutrition. I allude to the mother's influence on the fœtus. The fœtus is chloroformed when the mother is; it undergoes the influence of all her sensorial excitations (Féré), and seemingly in some cases even moral action is shown. Theoretically I have ever held this fact to be one of necessary sequence, and I might even cite some convincing observations of my own; but the question has, on the whole, received so little serious study that I purposely leave it out.[3]

Another kind of transmission, a little more remote still, is hereditary transmission,[4] which is psychical as well as physical. A strange fact! Hereditary transmission is generally accepted, because there is a drop of albumen to be its vehicle and to afford a sort of basis for our imagination, while people refuse to believe in transmission by contact; as though it were easier to conceive of a series of moral tendencies and aptitudes being locked up in a drop of matter! Take, for instance, the case observed by Mr. Brown-Séquard: it will at the same time serve as an example of the inverse action of the fœtus on the mother:

"The fact recorded by Dr. Harvey, of Edinburgh, as having been observed in man and in certain animals, was very clearly presented in the guinea-pig. The mother was modified physically so as to resemble the father. Male guinea-pigs in which the cervical

[1] See Notes on Ideoplasty in the Appendix.

[2] For the influence of the brain on the other organs, see the excellent work of Dr. Hack-Tuke, "Body and Mind."

[3] Certain pointers are to be found in two interesting works, one written by a distinguished physician and strong scientific skeptic, Dr. J. B. Demangeon: "De l'Imagination Considérée dans ses Effets Directs sur l'Homme et les Animaux," 2d ed., Paris, 1829; the other by an enthusiastic but *spirituel* schoolmaster, Frarière: "Éducation Antérieure, Influences Maternelles," etc. Paris, 1862. See also the chapter devoted to this question in Dr. Liébeault's excellent and classic essay, "Du Sommeil et des États Analogues," Paris, 1866.

[4] See Ribot, "Psychological Heredity." 2d ed. [Ribot's "Heredity" was done into English by the translator of the present work.]

sympathic nerve had been cut begot young that presented the effects of the severing of that nerve, and the mother, too, at the time of littering and afterward, showed the same effects."

So, then, the operation was performed on the sire, but the dam underwent the action! Is that in any degree less astonishing than nervic contagion or mental transmission?

At bottom all these phenomena are one. A drop of albumen as an intermediary is not more comprehensible than mere contact, or the environing media as intermediaries. In nature there are no absolute limits, all things are linked together in a gradual evolution. If the dam can become like to the sire through a physiological transmission; if the embryo, after inheriting from the sire, can communicate its malady to the dam; if nervous diseases are heritable, whether with or without transformation; if epilepsy in the child can be the sequel of insanity in the parents, or insanity in the child the sequel of epilepsy in the parents, then why should not the case be the same with regard to a close contact between two individuals—a contact much broader and much more direct than that of a spermatic corpuscle, which, after all, is not absorbed by the dam, but, on the contrary, is nourished and is transformed at her expense.

And nervic contagion once accepted, we are in the region of mental suggestion, and we reach it, as has been seen, by a series of intermediate phenomena: transmission of healthiness, of sensations of the magnetizer, of sensations of the subject, transmission of the sense of exhaustion, of aches and pains, of objective sensations, of emotions, of thoughts, and of will. Will-action at a distance is but the last term of a long evolutional series.

And at the bottom of all this there is but one thing, the same thing that underlies the relation of the magnet to iron, of the sun to the earth: transmission and transformation of motion. It remains only that we point out the applications.

What? Can mental suggestion have any practical application? When I began this study, I little thought myself that it could have; I supposed I was dealing only with questions of pure theory, and so, in accordance with Mr. Taine's dictum, when I came upon a new truth I cared but little to know whether it was of any use or not. But certain facts lately observed seem to be of a sort to justify an immediate application.

First, I would remark that the moment you admit the reality of mental suggestion you must make amend of honor to the magnetizers and reserve to that influence a certain part in the general practice of magnetism. One must not act like a machine, but must superadd to the suggestive or the physical action the influence of a concentrated thought and a firm will. True, the act is performed habitually without attaching any importance to this point, even without thinking of

it. But they who hypnotize often, or who parade their own purely subjective theories, neglect this resource, and then it happens, as it has happened to me, that they do not obtain all the results they might. For example, I put a question to an endormed patient that has always answered me readily. But it happens that to-day she is in a profounder sleep than usual; so, despite my reiterated questioning, she makes no reply. Supposing that there might be some contracture of the vocal muscles, I set them free by a few passes, but the patient still made no answer. The patient's right arm stirred, as though she wanted to write, so I set the arm free and gave her a pen. She wrote this word: "*Veuillez.*"[1] I did not understand her meaning and was annoyed, as she was also, still remaining aphasic. At length I said to her with more psychic energy: "Answer me; I want you to answer." She then replied and explained to me that she had been powerless to speak because I had not willed it with sufficient firmness.

On another occasion I had a patient whom it was very difficult to hypnotize, and in whom somnambulism did not manifest itself till after three months' treatment. After a few days some progress was made in endorming her, but thereafter for a whole year her sensibility remained *in statu quo*. It always took ten or fifteen minutes to endorm the patient. It was tiresome work, but I resigned myself to it and performed the passes listlessly. When a year had passed it occurred to me to add to the action of the "regard" not only a show of will but a positively stronger exercise of will-power, and in less than half the time the patient was endormed.

True, in this particular case, had I employed the same means earlier, I should probably have had no better success. The patient was insensible to all the finer magnetic agencies. But about the time referred to I noticed with astonishment that she was becoming sensitive to the magnet (sensitive, I mean, apart from the influence of the imagination, for under that influence she was from the first slightly sensitive to the hypnoscope). The magnet, when placed near her arm while she was in lethargic aideia, produced, for the first time, a general contracture. This it was that gave me the idea of trying mental action, which, by itself, never had any effect upon her, but which materially assisted the action of the hand or of the eye.

I know that in the great majority of cases mental action will be of little avail; but as one never knows when it may begin to be efficacious, one will do well to try it.

So, too, we must make use of it in therapeutic applications, and not make light of the advice of magnetizers, who require of the operator a certain moral sympathy with the patient, and a strong desire to do him good. We must take account of our physical and psychic state

[1] Imperative mode of the verb meaning *to will*, "exert will."—*Translator.*

at the moment, so as not to transmit to the patient an indisposition or a sense of depression.

Such are the general applications, but these are not all. Certain other facts have suggested to me a more special application.

At first I supposed (and the supposition seems entirely logical) that where verbal suggestion fails, mental suggestion will, *a fortiori*, be of no use.

That is a mistake. Mental suggestion may be of use, and even of great use.

It happens sometimes, particularly in nervous and mental complaints, that some subject, on being recalled to the patient's mind, produces untoward results. Yet, in some way or other, the matter has to be settled. A sensible physician knows how to deal with the natural or the morbid susceptibilities of his patient, and goes to work in a roundabout way. He brings the patient round by degrees. But very often this is of no avail, especially in somnambulism; the recollection of the most trivial circumstance may precipitate a paroxysm, the most trifling order looking in a given direction may excite opposition. Now, it is just in such cases that I have found mental suggestion of great use. I would add that the two subjects on whom I tried this experiment were not suggestionable directly, whether by speech or by mental action. In one case the question was about removing the patient's bed to another apartment. For certain reasons it was impossible to make the patient consent to the change, which, nevertheless, was intended for her own good. One day as I sat by her, she being endormed, I kept thinking for ten minutes at least, "You are going to have the bed taken into the other apartment;" "The bed must be taken into the other apartment," and so on. A few minutes afterward she began to talk with me about different things, and then suddenly, of her own accord, brought up the question of the bed without any excitement at all; for ten minutes she discussed the matter, and at last showed a disposition to agree to the change. Knowing as I did the conditions, I was almost sure that mental suggestion had had something to do with her sudden change of mind; but, to remove all doubt, I made another experiment. So again for about ten minutes I kept thinking, "You are going to put your right hand on your head;" "Put your right hand on your head," and so on. Immediate action there was none; but a quarter of an hour afterward she put her right hand on her head and kept it there for ten minutes, without any reasonable cause.

The reader recalls another case like this one, that of Miss Z. (p. 97 *supra*), who would not go to bed, and who, after withstanding all sorts of verbal persuasion, succumbed to a suggestion not expressed in words, to a *retarded* mental suggestion.

On the whole, my latest observations seem to prove that retarded

mental suggestion is far more common than one might suppose, *i. e.*, that it may succeed where immediate direct action is absolutely null.

That is a result that assuredly will have weight, should it be confirmed by wider observation.

Finally, we may remark that with subjects with whom direct suggestion is possible, the therapeutic application may be made whenever a train of mental associations is to be broken or another train to be set up without the subject suspecting your intention, for, as we know, the mental suggestion may be entirely unnoticed : the subject, though he obeys it, still thinks he is acting from his own personal motives.

Shall I say anything about theoretical applications? They are very many. A multitude of facts hitherto inadmissible may, nay must, henceforward be examined seriously. In short, psycho-physical transmission may be able to account for :

1. Certain cases of instinctive appreciation of diseases ;
2. Certain cases of direct nervic contagion ;
3. Certain illusions of observers that have not guarded against a mental influence ;
4. Certain cases of alleged second-sight ;
5. Certain phenomena of veridical hallucination, hard to believe, but in some instances well attested ;
6. Communication of certain sensations in the dreams of normal sleep ;
7. The alleged divinations of "rapping spirits ;"
8. The mysterious influence of certain personages ;
9. The difference between one "hypnotizer" and another ;
10. Sundry facts recorded in the history of civilization and credited to demons, oracles, sorcerers, obsessed persons, etc.[1]

[1] Here is an alleged case of psycho-physical transmission of a kind not mentioned by our author, and the reader may set a big interrogation point over against it, but let him recall Arago's dictum :

"The strange case of a north-western Kansas girl is attracting much attention. Her life will be studied at the summer meeting of the English Psychical Society. She is Mary Vennum, a resident of Rawlins County, and it is believed that she has lived two lives.

"The Vennum family lived near a family named Koff. The latter had a daughter about the age of Mary, who died of epilepsy. Mary Vennum was also subject to this disease.

"While she was suffering from an attack the Koffs called on her, and were startled to see how closely she resembled their daughter. After many hours of suffering Mary came out of her fit, and, although she was not changed in feature, she seemed entirely changed in mind.

"To all intents and purposes she became Mary Koff. Where the latter's life was broken off she took it up, and she was allowed to go and live with the Koffs, her family hoping it would cure her. She was perfectly content in her new home, and from the moment she stepped inside the door seemed familiar with the household. Though she had never visited the house before, she seemed to recognize the belongings of the dead girl as her own. On one occasion she ran through the house, saying :

"'Mother, where is my pink cape?'

"But will not that be simply a revival of occultism and magic?"

Precisely so. Nor shall I complain, for this occultism and this magic come back *as a science.* They may regenerate science. Latter-day science is slightly at fault for lack of imagination. She has become "routinized," has shut herself up in a bleak and arid region, has puttered with petty details, petty measures, and petty formulas, all highly useful and necessary; but they never can constitute a *science.* A science is not complete without a general conception, that is, a philosophical conception. In the past the philosophical imagination was so misused, we think it our duty to do entirely without it. Men think that the scientific positivism that debars the study of "efficient" causes and "final" causes as in fact beyond our ken *in our present stage of evolution,* must debar such study forever, and not only that, but the study of every alleged phenomenon that seems visibly to lie beyond the boundary of our knowledge.

Such prejudice is to be condemned. The old unscientific systems are dead, and that is well; but it is not well that no better system has come to take their place. We must advance with all caution, but we must *advance,* not only with regard to minor observations, but also with regard to a *philosophic conception* that shall steadily become broader, bolder and more profound.

Now, we shall never attain a view of the sum of phenomena unless we free ourselves from the routine of the schools, and unless we attack manfully the problems of occultism and magic.

For, take note, the sensist doctrine itself holds that man does not invent problems, but derives them from his experience. Magic is only an experimental science set on a wrong basis, distorted, incomplete, degenerated—what you will: yet a science *in its beginnings* experimental. Let us take up anew these studies with the improved instrumentalities that we possess, with the precise methods we are so proud of, and we shall see a progress we look not for take its start from this alliance between the past and the present—we shall see a new Renascence. I am mistaken or it is already begun.

The great discoveries and inventions of these latter years bear the stamp of the marvelous as well as of strict method: disks of metal and light-rays are made to speak, we make chemical analysis of the heavenly bodies, we attack the problem of electric vision at a distance, we bring to the front again the medical lore of the exorcists and the miracles of the *stigmatizati,* we exhume the ancient spiritism, we go

"'What do you mean?' asked Mrs. Koff, and then she rembered that her daughter had had a pink calico cape, which she wore before she died. Again she inquired:

"'Where is Gyp? I want to see him. I am afraid he has not been properly cared for.'

"Gyp had been the favorite dog of Mary Koff, and had been dead for six years. His name had never been mentioned before Mary Vennum, and Mrs. Koff does not remember having ever spoken of him since their acquaintance with the Vennums."—*Newspaper telegram, dated Abilene, Kan., July* 3, 1891.

back to the amulets of metallotherapy, to the massage of olden priest-craft, to the magic formularies of the Orient.

So much the better! I like well to see this awaking of a spirit mature and strong to the phantasies of youth. Can it be that we are not quite so sure of the soundness of our logic, of our mental equilibrium, and of our positive tendencies, rooted as they are by the experience of a century, as not to be afeared of an outbreak of mysticism?

No! Occultism is not a source of danger to civilization in that it exists, but in that it has possessed itself of some rays of light which science does not strive to regain for itself.

Clearly there will ever be unkempt enthusiasts whose delight it is to contemplate the vague and the obscure. But it is not such as these that keep alive popular errors and prejudgments. Those errors are kept alive by the aspirations of those who, dissatisfied with a science that only makes darkness visible, look for a clearer light, and seek it after the manner of night-flitting moths: they singe their wings.

An intelligent physician, of lively imagination, a sincere inquirer, but a skeptic from scientific routine, attended a spiritist seance. He went there to oblige a friend, not even out of curiosity, being convinced that the whole thing was "imposture or illusion." With a smile on his lips he put a few questions to the "spirits," just to expose the stupidity of mankind. But the "spirit" took his revenge. The medium's unconscious divined his thoughts, and our skeptic was confounded, amazed, and like an honest man published the truth. Inasmuch as science has never troubled itself about the phenomenon of mental suggestion, he knew nothing about it, and believed it impossible; so he fell into mysticism, became a spiritist, and is engaged in propagating the contagion.

Science lost a useful man. Why? Because from vanity, or from over-confidence, it disregarded the discoveries of its fallen rival.

No; mental suggestion does not favor occultism, on the contrary it banishes it. And once recognized, once regenerated by positive science, it will interpret to us, in language more forceful and more worthy of our age, the mysterious echo of ancient truths.

APPENDIX.

I.

NOTE ON A CRITERION OF HYPNOTIC SENSIBILITY; THE HYPNOSCOPE; A NEW METHOD OF DIAGNOSIS. By J. OCHOROWICZ. Presented to the (Paris) Biological Society by Mr. CH. RICHET, May 17, 1884.

I have the honor to present to the Society the results of my researches made in 1880-82 in the University of Lemberg, in Cracow, in Warsaw, in the Tatra mountains, and during the last two years in Paris. As I consider them to be of some practical value, I propose to give a brief account of them before publishing the observations in detail. I will point out the advantages to be gained for physiology and medicine from the physiological action of the magnet. That action, as I am well aware, is by no means accepted by all; but from the *empiric* point of view, which I am at this moment taking, I can leave to the reader the liberty of looking on this action as purely psychic or suggestional: the results will be none the less true, none the less important.

The form of magnet that I have definitively settled upon as the best for practical use, is much like Joule's electro-magnet, differing from it in that in mine the lines of force are inside instead of outside of the magnetized tube. To distinguish the style of magnet that I employ from all others, to avoid repetition, and to indicate the purpose for which it is used, I call this little apparatus a "hypnoscope." I hope it will, before long, find its place in medical practice alongside Weber's æsthesiometer.

The advantage gained by the use of the hypnoscope is twofold:

1. It gives us the criterion of hypnotic sensibility, *i. e.*, facilitates greatly investigation of the phenomena of hypnotism;

2. It gives to the physician a new means of diagnosis in nervous disorders.

The mode of applying it is as follows: the index finger of the person to be tested is introduced into the tube of the hypnoscope so as to touch both poles at once; after two minutes the finger is withdrawn and the effects produced in the finger are examined.

In seventy persons in one hundred taken at random no change will be observed. In about thirty, two kinds of effects will be noticed: subjective effects and objective. The former consist of subjective sensations, chiefly these: a feeling as of a breath of cool or warm air, a tingling or pricking sensation, a feeling as if the skin were puffed out, numbness of the muscles, pains of different kinds, a sense of heaviness in the finger or in the whole arm, etc. The objective effects belong to one or other of these three categories;

1. Involuntary movements: uncontrollable tremor of the index finger, or of the whole arm;

2. Insensibility more or less pronounced, analgesia, anæsthesia, especially in the tip of the finger, sometimes in the whole arm;

3. Paralysis and contracture, more or less manifest, amounting sometimes to complete rigidity; elastic rigidity (what Nélaton calls *doigt à ressort*).[1]

The phenomena thus produced disappear after a few minutes under very gentle massage; without massage they may continue for several minutes, or even for several hours.

There is a constant parallelism between this faculty of being influenced by a magnet and *hypnotic sensibility*. All persons who show sensibility to the magnet are more or less hypnotizable; all other persons are refractory.

The number and the degree of the effects, subjective and objective, correspond to the degree of the person's hypnotic sensibility. Whenever the subjective and objective phenomena are easily produced, one may infer a high degree of sensibility; the sensibility is small when but one of the three classes of effects is exhibited, or when the effects are but little marked. But one must be on his guard against purely accidental sensations produced by emotion. These are easily recognized, for the true sensations always reappear when the test is repeated, while the imaginary ones disappear, or change their character at the second trial.

The few exceptions to the above-mentioned general rule can always be traced to secondary causes, and rather confirm the rule. It is known, for instance, that the *habit* of being influenced by *stimuli* of a definite kind enhances the sensibility for that sort of *stimuli*, and so it may be that a person that has been frequently hypnotized by a given method will be relatively *less* sensitive to the magnet on the first trial; but we have only to take the same course with the magnet in order to bring out the normal parallelism, as is seen when after the hypnoscopic test hypnotization is tried for the first time.

I would remark further that hypnotic sensibility on the one hand, and magnetic sensibility on the other, may be modified, or even done

[1] Literally "finger with a spring," *i. e.*, one that when bent springs back to its original posture, as if it were actuated by a spring.—*Translator.*

away by *suggestion in the monoideic state.* Nor must it be forgotten that "hypnotic sensibility" is not synonymous with "somnambulism with loss of memory." The latter phenomenon cannot be produced in more than about 15 per 100 of subjects, while with 15 per cent. more several phenomena can be obtained without complete sleep.

It happens even that we may by the aid of the hypnoscope discover a very high degree of sensibility, restricted, however, to inhibitory phenomena of muscles, and in that case the subject will be readily hypnotizable in the sense that it will be possible to tetanize him completely, though we may be unable to endorm him. More rarely we observe with the aid of the hypnoscope *insensibility alone*, and then, too, it is difficult to produce sleep, and impossible to produce contractures.

In short, the hypnoscope reveals to us a special nervic aptitude peculiar to a relatively large number of persons who enjoy, or seem to enjoy, perfect health. This aptitude is not synonymous with general nervousness, for a good many exceedingly nervous persons are refractory to the action of the magnet and to hypnotization, while we find excellent subjects among those who are not at all "nervous." Women in vigorous health have in general less sensibility than men, but among persons suffering from disease the women have by far the greater sensibility. Sometimes the proportion is, for women, 45 per cent.; for men, 35 per cent. But it is certain that in nervous disorders the hypnotic sensibility is great, and that of the victims of the major hysteria but few are refractory.

Nevertheless, we must not confound hysteria, epilepsy, neurasthenia, still less anæmia, with hypnotic sensibility, which is a complex aptitude, but *sui generis.* It probably depends on special reflex relations subsisting between the cerebro-spinal system and the ganglionic system, and, above all, between the brain and the vasomotor nerves.

It remains that I make a few observations upon the use of the magnet as an instrument of diagnosis. A simple hypnoscopic experiment of itself gives us a deep insight into the mysteries of the patient's nervous system. It brings out in a minute all the weak points of his nervous organization, one after another. If there is any functional anomaly whatever, the patient will for a moment feel pains, or will be seized with convulsions; complaints that are past and gone, and that for years have made no sign, make their appearance for an instant in miniature; the tendencies of nascent diseases are revealed; epileptics feel the oncoming of an attack (but the actual attack is even thereby deferred and made milder); we are enabled readily to distinguish functional anæsthesis or paralysis from organic, for the former begins to disappear under the magnet, and where the complaint is clearly organic there is always hope of betterment when the hypnoscope produces any effect at all. In many cases of paraplegia we are able

to determine exactly the limits of the spinal lesion by passing a magnet along the vertebral column. In some cases of neuralgia and of paresis, the magnet produces heat on one side and intense cold on the other, thus indicating exactly the sensor or the motor nerves affected by the disease, and so on. Hence it would be an unpardonable negligence were one obstinately to reject this harmless agency—one, too, so instructive—on the pretext that the physiological action of the magnet is as yet unknown. In the revelations of the hypnoscope I see the necessity of a discrimination in therapeutic. It begins to be seen that it is useless, or even imprudent, to apply the self-same remedies to sensitive patients as to those without sensibility. With very many hypnotizable patients remedies are all equally good or equally bad, according to the particular nervic influences. We can *by suggestion* neutralize the strongest doses of the most typical medicines, and again by suggestion we can produce their typical effects in the most unmistakable way. With sensitive patients we often bring about a change for the better in an instant by means of a number of simple operations that hypnotism and magnetism place at our disposal. Will physicians still insist on administering poisons which do injury even when they cure?

II.

ON IDEOPLASTY; THE FACTS CLASSIFIED. Note by DR. JULIAN OCHOROWICZ, presented to the (Paris) Biological Society, June 21, 1884.

Ideoplasty[1] signifies physiological realization of an idea. It includes all the phenomena that come under the term (vocal) "suggestion," and also all similar phenomena produced without the intervention of a second party, *i. e.*, all the phenomena of "self-suggestion," or "spontaneous suggestion." Thus we have ideoplasty whenever the thought alone of any functional modification determines such functional modification.

The phenomena of ideoplasty are but instances of the action of a general law, to wit, the *law of reversibility*. All transformations of force are reversible. If heat can produce mechanical motion, so mechanical motion can produce heat. If electricity produces magnetism, magnetism too can develop electric currents. If the voice can cause undulatory currents, so can such currents reproduce the voice; and so on. This law is of the highest philosophic importance, because it enables us to foresee the inverse transformation once the direct transformation is verified; and it often happens that the transformation of *a* into *b* is fully known, while the transformation of *b*

[1] The word was first employed by Dr. Phillips in a slightly different sense. See his "Cours Théorique et Pratique de Braidisme," p. 44, *sqq*. Paris, 1868.

into *a* has yet to be made out. For example, the phonautograph (mechanical motion caused by speech) was known for a long time before any one dreamed of the possibility of an inverse transformation, *i. e.*, the reproduction of speech by mechanical motion (the phonograph).

So then ideoplasty is an instance of the operation of this universal law of nature. Commonly it is the sensation that gives rise to the thought; in ideoplasty it is the idea that gives rise to the sensation. This inverse transformation is called *hallucination* when it occurs spontaneously, and we have habitually given to suggestion the name of artificial (*provoquée*) hallucination. In both forms there is *ideoplasty of sensations*, or *passive ideoplasty*. This may be either positive or negative. It is *positive* when it determines perception of an excitant that does not exist; it is *negative* when it renders perception of a real agent impossible. Phenomena of the former class are well known, those of the latter class not so well, but I have many a time had evidence that it is possible for example to render *invisible* to the subject, even in the waking state, a person, an object, or a portion of an object or of a person; so that the retina of the hypnotizable subject, even when awake, shall be absolutely insensible to a given object. And if, for instance, the magnetizer renders invisible a person that is smoking a cigarette, the person, the cigarette and the smoke will be invisible to the subject; but if the person lights another cigarette that has not been bewitched by negative ideoplasty, the subject will be amazed to see a lighted cigarette moving through the air.

Besides ideoplasty of sensations there is another kind of ideoplasty, which we shall call *ideoplasty of movements*, or *active ideoplasty*. Like ideoplasty of sensations, it may be either positive or negative. Examples: 1. The thought of yawning of itself produces yawning; or one suggests to a somnambulic subject any movement, and it is impossible for him to refrain from performing it. In this way we can, for instance, command the writing of a testament, or even the commission of a murder, nay, even suicide. In the state of monoideism, the object of the suggestion is indifferent, for the subject is totally incapable of resisting. Recent experiments have proved this, and the fact is beyond question. 2. So, too, we can *hinder* the performance of certain voluntary movements. You draw an imaginary line, for instance, and the subject finds it impossible to overstep it, not because of any momentary paralysis of the muscles, for they may remain supple, but because of a *momentary amnesia of the bodily movements* at a given instant; for there is psychic amnesia of ambulation just as there is amnesia of words. But it is the thought of the impossibility of movement that renders it impossible: this, therefore, is negative active ideoplasty.

The two categories just mentioned do not include all the phenomena of ideoplasty. There is a third, which embraces facts that are truly surprising: this we shall call *material* (or *trophic*) ideoplasty. We have to do now, not with a subjective sensitivo-motor effect, but with a real, an objective change in the vital functions, and in particular of the vegetative functions. Material ideoplasty may also be either positive or negative. It is a common thing for a person after receiving a burn mentally to represent to himself the pain of a burn, but is it possible for the idea of a burn to produce an actual local inflammation?

However improbable that may seem, it is none the less true. By dint of protracted passive ideoplasty, local inflammation may sometimes be produced, or even a blister; and inversely I have in one case succeeded in dissipating, by means of suggestion in the hypnotic state, a very definite dental fluxion of two days' standing. Beginning with passive hallucinative ideoplasty I procured the complete disappearance of the boil in 25 minutes. These experiments account for the extraordinary fact of *stigmata*, and they are well worthy of being repeated by other magnetizers. Again, we can, by prolonged suggestion, produce not only the sensations of heat and cold, but also an actual increase of the surface temperature. In one instance I obtained a diminution of 0.9°,[1] and the diminution lasted several hours. So, too, we can lessen or increase the rate of pulsation, the secretions, and in general the physiological exchange of matter. We can give the subject a prodigious appetite and cram him for hours. We can at pleasure fix with precision the duration of natural sleep, and can cure insomnia. Finally, we can alter for several weeks the appetences and the moral character of a subject. It is impossible to cite here all the facts observed by me, but these will suffice, I hope, to win the attention of physiologists.

And just as we can produce material modifications in the functions of the subject, so, too, we can *save him* from influences that else would produce certain functional modifications. This is an instance of *negative* material ideoplasty. It is possible, for example, by simple suggestion in the state of monoideism, to render the subject totally refractory to a strong dose of alcohol, opium, morphine, or the like. I venture even to hold the opinion that the effect of a lethal dose of poison might at least be reduced; and it would be well to try this method of psychic inoculation in cases of hydrophobia and of cholera when the patients happen to be hypnotizable subjects.

In general, in all the three categories of ideoplasty, just as it is possible to produce certain pathologic functional changes, so it is often possible, too, to cause them to disappear when they arise spontaneously as diseases. This is mind-cure, and it has been unjustly neglected.

[1] Centigrade.

Persons who are sensitive to ideoplastic influences are keenly sensitive to the hypnoscope.

I reserve for a future communication a sketch of a psycho-physiological theory of ideoplasty.

III.

ON THE THEORY OF IDEOPLASTY. Note by Dr. J. OCHOROWICZ, presented to the (Paris) Biological Society, June 28, 1884.

According to the classification set forth in my preceding communication, three categories of ideoplastic phenomena may be distinguished, viz.:

1. Ideoplasty of sensations: positive and negative;
2. Ideoplasty of movements: positive and negative;
3. Material or trophic ideoplasty: positive and negative.

It remains for us now to explain the facts. Explaining means reducing an isolated fact to known conditions that suffice and that are necessary. The conditions of ideoplasty are twofold: psychic and physiological.

Psychic Conditions. Ideas may be regarded as in a certain sense *forces.* They are linked together by associations, and their action, as a rule, is manifested inwardly only. If they are to produce an effect external with respect to the brain, there must be either an excitation from without or an *act of will.* In ideoplasty it is otherwise, the idea producing an effect without any sufficient external excitation, and independently of any act of will, sometimes even counter to excitations and will. Whence this autonomy of ideas? It comes of an increase of their intensity. The idea of a source of light, as that idea grows in intensity, becomes transformed into a sensation of light. The representation[1] of a movement, by becoming more intense, produces that movement; and so on. And what is the cause of this increase of intensity? This: ordinarily an idea never presents itself alone, but is always associated with a group of other ideas. While I am thinking of a lion that I do not see, I see the paper on which I am writing these words; I see my hand, the pen, the writing; I am conscious of the position of my members; I hear the noises of the street; and so on. All these ideas, sensations, and representations are pictured in my mind with more or less distinctness. The greater their number, the less distinct are they, for they rub one another out, paralyze one another. When I concentrate my thought upon a distant sound, I catch that sound more clearly; but at the same time I

[1] *Representation* here = *idea* above. Both terms are used by the author to mean the *residuum* of a sense-impression in the mind when the outward object no longer presents itself actually to the senses.—*Translator*

am relatively insensible to other sounds; and often while we wait impatiently for a signal that has been agreed upon to be given, we get it through ideoplasty before it has really been given. Hence it is through an *isolating of the attention*, by elimination of extrane ideas, that the dominant idea gains its exceptional intensity. It is stronger than usual because it stands *alone*, and because it meets no obstacles within. I may, while writing, represent to myself the act of yawning, and the representation will rest in my mind as a mere recollection of a reflex movement, being counterbalanced by other ideas; but if, having nothing to occupy my thoughts, I contemplate passively a person that is yawning, I myself shall begin to yawn through imitative ideoplasty. In all cases of ideoplasty one psychic condition is essential: to wit, there must be a marked tendency toward monoideism, *i. e.*, toward isolation of the dominant idea. Otherwise that idea will remain weak, and will be unable to translate itself into a sensation or a motion. Material ideoplasty betokens a still more pronounced state of monoideism. Material ideoplasty cannot be produced save in the perfect hypnotic state (though that be but momentary), and by vigorous and prolonged monoideic action. Then it is that the idea attains the maximum of its potency, and reigns supreme. All extrane sensations are done away, and the mind is become *tabula rasa* whereon the suggested idea is reflected with unwonted intensity. The dominant idea then controls the entire nervous system.

But how can the idea of a hæmorrhage, for example, which is simply something subjective, mental, produce actual hæmorrhage, which is an objective, material fact? To understand that we must consider the physiological conditions.

Physiological Conditions.—Doubtless the trophic changes produced by material ideoplasty are brought about by the agency of the vasomotor nerves. A super-excitation or a paralysis of these nerves in their different combinations, might account for them more or less fully. But how comes an *idea* to influence the vasomotor nerves? Strictly speaking, it is not the idea as such that determines these changes. The idea is but the starting-point of an action, not the agent properly so-called. And here I desire to call attention to a class of associations highly important, but not much studied. It is not to be supposed that only *ideas* associate with one another. There are also psycho-physical associations between ideas on the one hand, and certain organic states on the other. These states, which are physiological complexes of great diversity, never reach the consciousness: we can move one finger or another, albeit we have no notion either of the nerves or of the muscles, or of the nerve currents that have to come into play to produce such movements. It is *ideorganic association* that sees to the execution of our will. This association is

partly hereditary, partly acquired, but even so far as it is acquired, it is still unconscious; only the first link of the chain, to wit, the idea, reaches the conciousness. Now, in material ideoplasty we have to do with associations of this sort. On the one side is the idea of a change; on the other an organic complexus that effects the change. And as, in the reproduction of ideas, the idea that is present awakens a past sensation or a past movement, so here the dominant idea calls up some particular organic state wherewith it is in unconscious association. We have here a sort of memory, but an unconscious, a materialized memory.

And a right strong memory it is. If, on the one hand, pathological states of organs may determine morbid ideas in the brain, on the other hand, in virtue of the law of reversibility, ideas favorable or unfavorable to health may mend or mar the general state of the organism. The influence is perfectly mutual, for *it is exerted between two links of one same chain of association.* Sometimes a mere change of surroundings suffices to produce a betterment; for, in a given place, everything, however indifferent in itself, is, in an unconscious way, associated with a morbid state, and tends to produce it, to maintain it, favors its continuance *through ideörganic association.* There are persons (the fact has been noted by Boerhaave) in whom the idea of a disease, the exact representation of its symptoms, suffices to determine the disease itself—the real ailment. That is an extreme case, but the agency that there comes into play remains. When some one tells us of a "stifling heat," we understand well what he is talking about, for the idea of heat calls up in us the physiological state of being heated. Suppose a greater degree of sensibility, an exceptional power of ideorganic reproduction, and you shall see an actual rise of the subject's temperature. If it is true, as has been well remarked by Mr. Brown-Séquard, that the phenomena of hypnotism are but manifestations of inhibition or of dynamogeny, then the phenomena of ideoplasty are only facts of inhibition or of dynamogeny conditioned by an ideorganic association, while the other cases of inhibition and dynamogeny depend on associations purely physiological—*inter-organic.* If, for example, excitation of the splanchnic nerve arrests movements of the intestine, that is because these two phenomena apparently so far apart—irritation of the splanchnic nerve and paresis of the muscles of the cœcum—are, in some way more or less unknown, physiologically associated, as a given feeling or sentiment is associated with certain expressional movements. The theory of inter-organic and ideorganic associations do not, it is true, explain what unfortunately remains unexplainable in the present state of our knowledge, to wit, the real *cause* of most of these associations; still it may, at all events, I hope, contribute to bring a number of highly diverse facts under one law and into one

associational mechanism. Psychology and physiology are thus brought together, and we can henceforth investigate the laws of physiological as we have already studied those of psychic associations. It is *when it loses its psychic associations* in the state of monoideism, that *the idea recovers its organic associations*, that it links itself to them, that it produces modifications in the organs with a force the more decisive and irresistible as it is itself potent and irresistible. It becomes confounded, so to speak, with the state it represents; it realizes it. One might say that cases of inter-organic inhibition are, for the most part, associations *by contrast*, wherein excitation of *a* is associated with inhibition of *b*; while cases of dynamogeny are associations *by likeness*, wherein an excitation *a* is followed by excitation *b*. And these associations may be causal, indissoluble, or they may be merely accidental; for, just as between ideas, so there are physiological associations *by contiguity*, that is, associations brought about by simple proximity in space or time. The morbid state *a* becomes associated with another morbid state *b*, through the mere fact that accidental causes have produced them, either simultaneously or one after the other. Thenceforth to call out *b* all that is needed is the presence of *a*. Such ideorganic associations *by contiguity* are often mistaken for causal associations. It is supposed, for example, that "the somnambulic state is induced by pressure on the top of the head," whereas between the two phenomena there is no causal relation.

In this brief notice I have had no other intention save to sketch roughly the general principles of a theory of ideoplasty. I have, therefore, purposely omitted any analysis of the special physiological conditions, as also any comparison of these general remarks with the theories of ideoplastic phenomena put forth by Braid, Durand, Charpignon, Liébeault and Bernheim.

IV.

Note to Chapter VII., Part II.

Mr. Bernheim makes this reply to my criticism:

"I said," he writes, "'No one can be endormed against his will.' Mr. Ochorowicz hotly contests that proposition. Probably he has not quite grasped my meaning. It is certain that a subject that is unwilling to be hypnotized, *and who knows that he cannot be hypnotized if he is unwilling*, successfully resists all efforts. It is true, also, that certain subjects are unable to resist, *because their will is weakened by fear or by the thought of a superior force that influences them in spite of themselves.*" (Bernheim, "De la Suggestion," preface, p. iv., 2d ed., 1888.)

Now, these provisos suffice to show that the exactitude of the proposition "No one can be endormed against his will," may rightfully be challenged. For, first, "the will may be weakened by fear, and consequently may be insufficient; and, secondly, the subject may not know that he cannot be hypnotized if he resists."

Now, we find exactly these two conditions in most cases of hypnotic constraint. A subject wants to resist, but has not the strength to resist. Or, one wants to resist, but is not quite certain that he can resist, and so he undergoes the action *against his will.* There is the principal condition! Faith, submission, the best will in the world to be hypnotized, are all of no avail in the absence of predisposition, *of hypnotic sensibility;* and incredulity and opposition do not suffice to safeguard the subject when there is predisposition, when he possesses in a high degree hypnotic sensibility.

One is not a somnambule because he wants to be; but those who are somnambules may be unable to resist, unless they have in their mind a sufficiently strong counter-suggestion. Unfortunately, the Nancy School confounds hypnotic sleep with normal sleep, and consequently overlooks the main rôle of predisposition.

Mr. Bernheim sums up by saying: "No one can be hypnotized, unless he has the idea that he will be hypnotized. Thus expressed, my proposition is impregnable."

By no means. The proposition is now nearer the truth, inasmuch as it covers a larger number of facts, but still it is inexact. Miss X. (chap. vii., part ii., obs. 1 and 2) did not know that she was going to be hypnotized. Hypnotized she was, nevertheless.

The same conditions are found in cases 4, 5, 6, 9, etc. It were nearer the truth to add that the *idea* of which Mr. Bernheim speaks may be *unconscious.* Thus filled out, is the proposition at last flawless? Possibly, but without entering on theoretic subtilities, we are obliged to affirm this much:

The facts prove that, given a sufficient hypnotic sensibility, an individual may be hypnotized in spite of himself and even unbeknown to himself.

M., Mrs., a magnetic subject, 60-76, 261; attempts suicide, 61
Magdeleine, Puységur's somnambule, 197
Magnetic attraction, 21, 26; currents, 25; fluid, 25; mobility, according to Puységur, 213; passes, 80; sleep, 11, 110
Magnetism and hypnotism differentiated: see *Hypnotism*
Magnetized subject, isolation of, 11
Magnetizer and stranger, difference between, for the subject, 10; and subject, 328; magnetizer's personality as a factor in magnetism, 324
Maricourt, Count de, and the somnambule, 187
Médecins, 110
Medical men's bigotry, 248
Mental action, conditions of, on part of operator, 324; on part of subject, *ib.*; on a waking subject, 325; mental sounds, 163; suggestion simulated, 23; suggestion, direct, possible only in one special somnambulic state, 77
Mesmer, his theory, 304; on metaphysical abstractions, *ib.*; different states of matter, *ib.*; the universal fluid, 305; why he used the term "animal magnetism," 306; inner sense, *ib.*; theory of will-transmission, 307; pre-sensation, 308
Microphone, its real action, 24
Mimosa pudica, 343
Mind-reading, 40
Minutes of a meeting, written in advance, 19
Mr. Camille, the story of, 39
Monoideism, 20; two phases of, 78; passive, favorable to mental suggestion, 78
Morin's theory of thought communication, 287
Mother and fœtus, sympathism of, 344
Motion transformed according to the medium traversed, 329; transformation of, 330
Motor images, 163
Muscles, tension of, betrays thought, emotion, etc., 59
Muscular suggestions, 338
Musical notes "magnetized," 262
Myers brothers, 83-90

Nascent monoideia, favorable to mental suggestion, 80
Nerve-action, producing electric currents, 341; currents, interaction of, 161; fluid, vital or magnetic, 299
Nervic contagion, 117, 135; equilibrium, 34
Nervous affections, contagiousness of, 314 *note*
Nervousness, not a condition favorable to magnetic action, 353

Newton, Isaac, on action at a distance, 312
Noizet, Gen., and the somnambule, 185
Nuns of Loudun, 167 *et seq.*, 262

Occultism and magic, sciences gone astray, 349
Ochorowicz, only of late a believer in mental suggestion, 10; experiments at Lublin, 10-14; at Warsaw, 15-20; at X., 20; at Lemberg (with Donato) 21
Odoriferous exhalations, 121
Odors, specific, of occupations, 124; of diseases, 122-126
Organic sympathism, its phases, 105

P., Count de, experiment with, 119
Pain, transmission of, 90, 135, 156
Passive somnambulism, 65
Perronet, Dr., observations on will-transmission, 209
Personality, alleged transfer of, 348, *note*
Petetin, how he was led to study magnetism, 176
Phonautograph, 333
Photophone, 334
Phrenomagnetism, 224
Physical action, direct, hypothesis of, 299; equivalents of psychic action, 322
Physiognomic, pathognomic and ideognomic signs, 59
Physiological transmission, 144
Piano played in catalepsy, 210
Playing cards, tricks with, 18
"Polarities," 38
Polyideism, 20
Poncet, 106
Popular opinions, 152
Præstigiation, 17
'Pre-sensation," presentiment, etc., 308,
Psychic atmosphere, 18, 21, 30, 44, 57, 320; contagion, 117
Psychic action, direct, 295; action, physical equivalents of, 322; personality, 11; states, theoretically transmissible, 34; states, revealed by odors, 123
Psychical Research Soc., experiments by, 157 *et seq.*
Psychology as yet an inchoate science, 57
Psycho-physical transmission, hypothesis of, 317
Puységur, his subjects, 110; his first experience of mental suggestion, 174; his theory of mental suggestion, 317; his prevision of modern theories of physics, 318; compares thought-transference to the action of an electric machine, 318

R., Miss, a magnetic subject, 30
R., Mr., a magnetizer, and his subject, 45-47
Radiophone, 261, 334
Rapport, 10; bi-lateral, 28; will-action and, 212 *et seq.*; diverted from the magnetizer, 215; does not exist in hypnotism, 218; what it means, 326; necessary for action at a distance, 338
Reading a book without aid of the eyes, 12–13

THE

HUMBOLDT LIBRARY OF SCIENCE

MENTAL SUGGESTION.

BY

DR. J. OCHOROWICZ.

PART I.

NEW YORK
THE HUMBOLDT PUBLISHING COMPANY
19 ASTOR PLACE

T OFFICE AS SECOND-CLASS MATTER.

NINTH EDITION.

HYPNOTISM:

ITS HISTORY AND PRESENT DEVELOPMENT.

BY FREDRIK BJÖRNSTRÖM, M. D.,

Head Physician of the Stockholm Hospital, Professor of Psychiatry, Late Royal Swedish Medical Counselor.

Authorized Translation from the Second Swedish Edition.

By BARON NILS POSSE, M. G.,

Director of the Boston School of Gymnastics.

Paper Cover (No. 113 of The Humboldt Library), - - - **30 Cents**

Cloth, Extra, " " " - - **75 Cents**

PRESS NOTICES.

The learned Swedish physician, Björnström.—*Churchman.*

It is a strange and mysterious subject this hypnotism.—*The Sun.*

Perhaps as concise as any work we have.—*S. California Practitioner.*

We have found this book exceedingly interesting.—*California Homœpath.*

A concise, thorough, and scientific examination of a little-understood subject.—*Episcopal Recorder.*

Few of the new books have more interest for scientist and layman alike.—*Sunday Times* (Boston).

The study of hypnotism is in fashion again. It is a fascinating and dangerous study.—*Toledo Bee.*

It is well written, being concise, which is a difficult point to master in all translations.—*Medical Bulletin* (Philadelphia).

The subject will be fascinating to many, and it receives a cautious yet sympathetic treatment in this book.—*Evangelist.*

One of the most timely works of the hour. No physician who would keep up with the times can afford to be without this work.—*Quarterly Journal of Inebriety.*

Its aim has been to give all the information that may be said under the present state of our knowledge. Every physician should read this volume.—*American Medical Journal* (St. Louis).

Is a contribution of decided value to a much-discussed and but little-analyzed subject by an eminent Swedish alienist known to American students of European psychiatry.—*Medical Standard* (Chicago).

This is a highly interesting and instructive book. Hypnotism is on the onward march to the front as a scientific subject for serious thought and investigation.—*The Medical Free Press* (Indianapolis).

Many of the mysteries of mesmerism, and all that class of manifestation, are here treated at length, and explained as far as they can be with our present knowledge of psychology.—*New York Journal of Commerce.*

The marvels of hypnotic phenomena increase with investigation. Dr. Björnström, in this clear and well-written essay, has given about all that modern science has been able to develop of these phenomena.—*Medical Visitor* (Chicago).

It has become a matter of scientific research, and engages the attention of some of the foremost men of the day, like Charcot, of Paris. It is interesting reading, outside of any usefulness, and may take the place of a novel on the office table.—*Eclectic Medical Journal* (Cincinnati).

This interesting book contains a scholarly account of the history, development, and scientific aspect of hypnotism. As a whole, the book is of great interest and very instructive. It is worthy of careful perusal by all physicians, and contains nothing unfit to be read by the laity.—*Medical and Surgical Reporter* (Philadelphia).

To define the real nature of hypnotism is as difficult as to explain the philosophy of toxic or therapeutic action of medicine—more so, indeed. None the less, however, does it behoove the practitioner to understand what it does, even if he cannot tell just what it is, or how it operates. Dr. Björnström's book aims to give a general review of the entire subject.—*Medical Record.*

Three Interesting Books at 25 Cents each, post-paid.

"SMOKING:"

A World of Curious Facts, Queer Fancies, and Lively Anecdotes about

PIPES,
TOBACCO,
AND CIGARS.

THIS is the most interesting, entertaining, and amusing book that has ever been published on the subject of "the weed."

It contains a vast amount of historical information and anecdote on the subject of Tobacco. Describes the various kinds of pipes that have been used and that are now in use in all parts of the world. Stories about the world's famous smokers; all about snuff and snuff-takers, etc.

It is an amusing miscellany of fact and anecdote relating to Tobacco in all its forms and uses, from its discovery to the present time.

Price, 25 cents, postpaid.

THE JOKER'S DICTIONARY.

Thousands of men, when in the society of ladies or gentlemen, want to be entertaining and amusing companions, but too often find that they cannot.

This great and original book comes to the aid of just such people; it does for the man who wants to be witty what Webster's Dictionary does for the man who wants to be wise in the use of words.

It is a perfect cyclopedia of wit and humor.

It contains 326 pages, six illustrations, and is arranged according to subject, alphabetically. That is to say, it is in the style of a dictionary. You can find Jokes, Stories, and clever bits of repartee, brilliant jests and flashes of merriment, on almost every subject likely to come up in social intercourse.

Price, **25 Cents**, post paid.

KISSING:

The Art of Osculation Curiously, Historically, Humorously and Poetically Considered.

This book, among hundreds of other things, tells all about the origin of kissing; gives the grammar of kissing; the scientific reason why kisses are pleasant; how to kiss and how to receive a kiss; the secret significance of kisses; all about lips, "the sweet petitiouers for kisses; an Irish kissing festival; the kissing customs of different countries all over the world; when you may kiss with impunity; famous kisses; the different kinds of kisses; how college girls kiss; stolen kisses, sometimes called "dainty bits of plunder;" curious bargains for kisses; excuses for kissing; kissing experiences; the important consequences connected with kissing; humorous stories of kissing in tunnels; men kissing each other in France, in England, and in Germany; origin of the custom of kissing the Pope's toe; Henry IV, and his punishment; kissing the feet of royalty, an ancient custom; kisses as rewards of genius; the part osculation has paid in politics; curious bargains for kisses; what legally constitutes a kiss; a kiss at auction; giving $50 to kiss Edwin Booth; excuses for kissing; how all nature justifies the practice; the childish and the humorous excuse; kissing casuistry; the gluttony of kissing; unaccountable osculatory demands; excuses for not kissing; Dominie Brown's first kiss; the kiss of the Spanish girl, the nurse, the mother; a curious German custom; Arrah-na-Pogue; refusing the sacrament on account of a kiss; how a child's kiss affects the course of a desperate man; what a little mare's kiss did; brought to life by a kiss; the kiss of death.

An exceedingly interesting book; a nice little present for a lady. Price ***25 Cents.*** For sale by booksellers; or sent postpaid on receipt of price.

Address: THE HUMBOLDT PUBLISHING CO., 19 Astor Place, New York.

MENDEL'S
COCOA

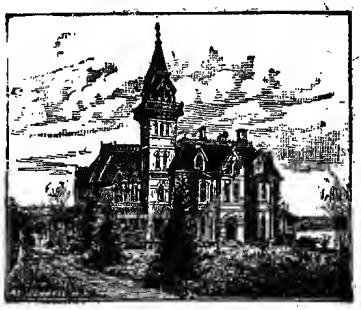
Without an equal in *Flavor*, *Strength* and purity.

A refreshing and delightful beverage, and a most nutritious food.

Is steadily superseding tea and coffee.

Everyone is benefited by its use.

ALL GROCERS.



Summer School of Languages.

AT BRYANT SUMMER SCHOOL, ROSLYN, L. I., N. Y.

For Ladies, Gentlemen, Collegiates, Teachers, Clergy, or Pupils of other Schools.

☞ Term—July 8th to Sept. 8th, 1891.

French three hours a day (optional); Music, Art, Sciences, Spanish, or other Languages in proportion. An excellent opportunity for cultured persons to spend the summer by the salt water, in the society of their own class, in a splendid building, with charming scenery, with much or little reciting. Good boating, bathing, sketching, cool nights, spring water, wide views of Bay and Sound, shady forest, 14-acre grove, cost $250,000. Write now for a summer outing in the most rural spot near New York. Invite your friends. Open all the year as a Collegiate and Preparatory School. *Delsarte System.* [For 18 beautiful new photographs of the School, write C. F. DeMott, Hempstead, L. I., with P. O. order.]

MENTAL SUGGESTION.

BY

DR. J. OCHOROWICZ.

PART II.

NEW YORK
THE HUMBOLDT PUBLISHING COMPANY
19 ASTOR PLACE

FFICE AS SECOND-CLASS MATTER.

NINTH EDITION.

HYPNOTISM:

ITS HISTORY AND PRESENT DEVELOPMENT.

BY FREDRIK BJÖRNSTRÖM, M. D.,

Head Physician of the Stockholm Hospital, Professor of Psychiatry, Late Royal Swedish Medical Counselor.

Authorized Translation from the Second Swedish Edition.

By BARON NILS POSSE, M. G.,

Director of the Boston School of Gymnastics.

Paper Cover (No. 113 of The Humboldt Library), - - - **30 Cents**

Cloth, Extra, " " " - - **75 Cents**

PRESS NOTICES.

The learned Swedish physician, Björnström.—*Churchman.*

It is a strange and mysterious subject this hypnotism.—*The Sun.*

Perhaps as concise as any work we have.—*S. California Practitioner.*

We have found this book exceedingly interesting.—*California Homœpath.*

A concise, thorough, and scientific examination of a little-understood subject.—*Episcopal Recorder.*

Few of the new books have more interest for scientist and layman alike.—*Sunday Times* (Boston).

The study of hypnotism is in fashion again. It is a fascinating and dangerous study.—*Toledo Bee.*

It is well written, being concise, which is a difficult point to master in all translations.—*Medical Bulletin* (Philadelphia).

The subject will be fascinating to many, and it receives a cautious yet sympathetic treatment in this book.—*Evangelist.*

One of the most timely works of the hour. No physician who would keep up with the times can afford to be without this work.—*Quarterly Journal of Inebriety.*

Its aim has been to give all the information that may be said under the present state of our knowledge. Every physician should read this volume.—*American Medical Journal* (St. Louis).

Is a contribution of decided value to a much-discussed and but little-analyzed subject by an eminent Swedish alienist known to American students of European psychiatry.—*Medical Standard* (Chicago).

This is a highly interesting and instructive book. Hypnotism is on the onward march to the front as a scientific subject for serious thought and investigation.—*The Medical Free Press* (Indianapolis).

Many of the mysteries of mesmerism, and all that class of manifestation, are here treated at length, and explained as far as they can be with our present knowledge of psychology.—*New York Journal of Commerce.*

The marvels of hypnotic phenomena increase with investigation. Dr. Björnström, in this clear and well-written essay, has given about all that modern science has been able to develop of these phenomena.—*Medical Visitor* (Chicago).

It has become a matter of scientific research, and engages the attention of some of the foremost men of the day, like Charcot, of Paris. It is interesting reading, outside of any usefulness, and may take the place of a novel on the office table.—*Eclectic Medical Journal* (Cincinnati).

This interesting book contains a scholarly account of the history, development, and scientific aspect of hypnotism. As a whole, the book is of great interest and very instructive. It is worthy of careful perusal by all physicians, and contains nothing unfit to be read by the laity.—*Medical and Surgical Reporter* (Philadelphia).

To define the real nature of hypnotism is as difficult as to explain the philosophy of toxic or therapeutic action of medicine—more so, indeed. None the less, however, does it behoove the practitioner to understand what it does, even if he cannot tell just what it is, or how it operates. Dr. Björnström's book aims to give a general review of the entire subject. —*Medical Record.*

Three Interesting Books at 25 Cents each, post-paid.

"SMOKING:"

A World of Curious Facts, Queer Fancies, and Lively Anecdotes about

PIPES,
TOBACCO,
AND CIGARS.

THIS is the most interesting, entertaining, and amusing book that has ever been published on the subject of "the weed."

It contains a vast amount of historical information and anecdote on the subject of Tobacco. Describes the various kinds of pipes that have been used and that are now in use in all parts of the world. Stories about the world's famous smokers; all about snuff and snuff-takers, etc.

It is an amusing miscellany of fact and anecdote relating to Tobacco in all its forms and uses, from its discovery to the present time.

Price, 25 cents, postpaid.

THE JOKER'S DICTIONARY.

Thousands of men, when in the society of ladies or gentlemen, want to be entertaining and amusing companions, but too often find that they cannot.

This great and original book comes to the aid of just such people; it does for the man who wants to be witty what Webster's Dictionary does for the man who wants to be wise in the use of words.

It is a perfect cyclopedia of wit and humor.

It contains 326 pages, six illustrations, and is arranged according to subject, alphabetically. That is to say, it is in the style of a dictionary. You can find Jokes, Stories, and clever bits of repartee, brilliant jests and flashes of merriment, on almost every subject likely to come up in social intercourse.

Price, **25 Cents**, post paid.

KISSING:

The Art of Osculation Curiously, Historically, Humorously and Poetically Considered.

This book, among hundreds of other things, tells all about the origin of kissing; gives the grammar of kissing; the scientific reason why kisses are pleasant; how to kiss and how to receive a kiss; the secret significance of kisses; all about lips, "the sweet petitioners for kisses; an Irish kissing festival; the kissing customs of different countries all over the world; when you may kiss with impunity; famous kisses; the different kinds of kisses; how college girls kiss; stolen kisses, sometimes called "dainty bits of plunder;" curious bargains for kisses; excuses for kissing; kissing experiences; the important consequences connected with kissing; humorous stories of kissing in tunnels; men kissing each other in France, in England, and in Germany; origin of the custom of kissing the Pope's toe; Henry IV, and his punishment; kissing the feet of royalty, an ancient custom; kisses as rewards of genius; the part osculation has paid in politics; curious bargains for kisses; what legally constitutes a kiss; a kiss at auction; giving $50 to kiss Edwin Booth; excuses for kissing; how all nature justifies the practice; the childish and the humorous excuse; kissing casuistry; the gluttony of kissing; unaccountable osculatory demands; excuses for not kissing; Dominie Brown's first kiss; the kiss of the Spanish girl, the nurse, the mother; a curious German custom; Arrah-na-Pogue; refusing the sacrament on account of a kiss; how a child's kiss affects the course of a desperate man; what a little mare's kiss did; brought to life by a kiss; the kiss of death.

An exceedingly interesting book; a nice little present for a lady. Price *25 Cents*. For sale by booksellers; or sent postpaid on receipt of price.

Address: THE HUMBOLDT PUBLISHING CO., 19 Astor Place, New York.

BY

ROBERT H. THOULESS

M.A., PH.D.

H&S

HODDER AND STOUGHTON

PUBLISHERS LONDON

First printed . . . . . June 1927
Reprinted . . . . . February 1928
First printed in this edition, March 1929

Printed in Great Britain for Hodder and Stoughton, Limited,
by Richard Clay & Sons, Limited, Bungay, Suffolk.

GENERAL PREFACE

THE object of HODDER AND STOUGHTON'S PEOPLE'S LIBRARY is to supply in brief form simply written introductions to the study of History, Literature, Biography and Science; in some degree to satisfy that ever-increasing demand for knowledge which is one of the happiest characteristics of our time. The names of the authors of the first volumes of the Library are sufficient evidence of the fact that each subject will be dealt with authoritatively, while the authority will not be of the "dry-as-dust" order. Not only is it possible to have learning without tears, but it is also possible to make the acquiring of knowledge a thrilling and entertaining adventure. HODDER AND STOUGHTON'S PEOPLE'S LIBRARY will, it is hoped, supply this adventure.

Contents

CHAPTER		PAGE
I.	SYSTEMS OF MENTAL DEVELOPMENT AND THEIR AIMS	9
II.	AUTO-SUGGESTION—ITS USES AND LIMITATIONS	27
III.	HOW HABITS MAY BE FORMED AND BROKEN	45
IV.	THE EMOTIONS AND HOW THEY MAY BE CONTROLLED	61
V.	THE INSTINCTS AND THEIR SUBLIMATION	81
VI.	CONCENTRATION	101
VII.	FATIGUE AND REST	121
VIII.	HOW WE REMEMBER	141
IX.	DREAMING AND REALITY	161
X.	INFERIORITY AND DOMINATION	177
XI.	THE DESTRUCTION OF THE INFERIORITY COMPLEX	195
XII.	MENTAL EFFICIENCY AND RELIGION	207

THERE are certain Indian ascetics, called Yogis, who practise a systematic development of their minds at the end of which they claim to be able to think about one thing alone or even to empty their minds of all thought. A particular kind of Yoga, called Hatha-Yoga, claims to produce in its followers perfect health and an ability to go on living indefinitely. It is claimed that it can produce even more remarkable results than this, and I have met an Indian student who assured me that he had often seen an old Yogi fly. It sounds surprising, but my informant was very certain about it.

The Buddhist ascetics practise an arduous system of thinking about the causes of desire and about life and death generally, which is supposed to result in the extinction of all desire and in the ability to keep the mind unoccupied by any thought whatever.

St. Ignatius Loyola has handed down to

us what are called the " spiritual exercises " —a system of meditation which had as its aim the strengthening of the religious sentiment. This has been the model on which most Christian systems of religious meditation have been founded.

Monsieur Coué teaches us to get rid of diseases by a method of auto-suggestion, which takes the form of repeating sentences to ourselves. He would have us say twenty times every night and morning: " Day by day, in every way, I am getting better and better."

All of these things—the Yoga systems, religious meditation and auto-suggestion—are what we may call *mental exercises.* They have very different aims, but they are all alike attempts to control the development of the mind in just the same way as dumb-bells control the development of the body. They are a kind of dumb-bells of the mind. Some of them are very strenuous, and would require the greater part of a lifetime to produce any results.

But mental exercises are not confined to these rather unusual things. Whenever we carry out any task of concentrated learning we are as truly exercising our minds as if we were

practising concentration by the method of the Yogis. Provided that the object of our learning is not that we want to be able to recall the particular thing learnt, but that we want to train our capacity for attention, we are as truly carrying out a mental exercise as a person who lifts a weight for the sake of developing his muscles is carrying out a physical exercise. A school child engaged in learning poetry, performing geometrical and algebraical puzzles, and so on, is carrying out a systematic course of mental exercises to fit his mind for the tasks it will have to perform when he has grown up.

Most of us give up the practice of mental exercising after we leave school, presumably because we are satisfied that our minds perform all the tasks that we demand of them to our complete satisfaction. If we are right in this conviction there is certainly no reason why we should bother ourselves with our mental development after our school days are over, but are we right? Do we never show any of the symptoms of mental inefficiency—worry, mind wandering, irritability, depression, or needless fears? The ideal of further mental development should not appear childish or futile to the

adult who is not free from these things. Psychology may still have something of practical usefulness to teach him.

Of course, normal people do not bother about their mental development. In truth, not very many normal people do physical exercises with dumb-bells at all systematically. Still fewer do any systematic exercises for their minds.

It does not appear to be true, however, that ordinary people are not interested in these things. A large number of methods are put forward which are claimed to make people happier, wiser and even wealthier, and anyone who announces that he is going to communicate such a system by means of a lecture can fill a large hall and arouse a good deal of enthusiasm amongst his hearers even if they do not systematically carry his precepts into practice. The lecturer, at least, can become wealthier, even if his audience are no happier or wiser.

Such a speaker is sometimes a man of rare and peculiar gifts. He may, however, have no qualification for guiding other people, except the doubtful quality of being able to carry conviction by a confident manner of delivery. It is quite likely that he has

nothing to tell his hearers which they could not have found out for themselves by consulting ordinary textbooks on psychology, such, for example, as William James's book on *The Principles of Psychology*, which may be found in any public library.

Of course this does not mean that the lecturer serves no useful purpose, because many people learn things by personal contact that they would never take the trouble to find out for themselves from books. But when such lecturers take high fees from people who can obviously not afford to pay them, and often give in return little but high-sounding promises, we cannot regard them as socially useful.

Why do people go to lectures which claim to tell them how to " overcome their limitations," to give them " a master-key to mental success," or " mastery of the world through self-knowledge," and why do they buy books entitled " Concentration," " Self-knowledge " or something of that kind? I suppose the answer is that the people amongst whom this demand exists suspect that their minds are not working at their fullest possible efficiency.

No doubt they are often right. They suffer

from worry, from mental inertia, from irritability and timidity, from sleeplessness, or from mind-wandering when they are engaged on some task which requires concentration. The attempt to get rid of such things as these by mental methods is as reasonable and sensible an aim as the attempt to get rid of one's bodily weaknesses by the use of dumb-bells. These are the kinds of mental defect about which we do not go to see the doctor. They are, however, a source of reduced mental efficiency, and we have not yet got a profession of " mental straighteners " (as suggested by Samuel Butler in *Erewhon*) to whom we can go to be treated for the minor ailments of our minds just as we can go to a doctor for a cold.

It may, therefore, be worth while to make a short survey of the methods of mental development which have been used at various times, in order to see whether there is anything of practical usefulness for the ordinary person which we can glean from them. We shall not take it for granted that any sort of mental gymnastics which have been tried by exceptional people in various parts of the world must necessarily be useful to ourselves. On the other hand, we shall not

make up our minds that any attempt at mental development is necessarily foolish for the ordinary person.

There seems no reason, on the face of it, why it should be more eccentric to use mental exercises for mental improvement than to use dumb-bell exercises for physical improvement. It is true, of course, that the use of dumb-bells can never really take the place in physical development of a free and healthy use of the muscles in hard out-door work. But dumb-bells are meant for the people who necessarily have an indoor occupation which makes it impossible for them to be developing their muscles in the original and natural out-door way. The same is true of the use of exercises for mental development. They can never be useful to those whose minds already work with perfect efficiency, and it would be absurd to suggest to the kind of brain-worker whose daily task makes him concentrate arduously all the time that he should do artificial mental exercises for concentration. His work will give him all the exercise in concentration that he needs. It is not, however, for such mental athletes that this book is written.

What scheme of mental development any

person carries out must, of course, depend on what ideal of mental attainment he considers a reasonable one. This question of aim is an important one, and we must spend a few minutes thinking about it. The difficulty does not occur in the same way with physical exercises. A man may, without doing himself much harm, spend ten minutes a day pushing dumb-bells about with no more definite idea than the vague one of developing his body. It is doubtful whether he could do anything useful at all in the way of developing his mind without a much clearer idea of what he was aiming at.

The Yogis taught a system of control by means of which a man could learn to think about nothing at all and could remain absolutely untouched by his affections and by the demands of outside things. The Stoics taught a more moderate discipline by which a man could be released from the bondage of his emotions so that he would be influenced by neither pity nor anger, though still (as in every other system) he was under the necessity of carrying out conduct for the good of his fellow men. No doubt, if we followed their methods we could become Yogis or Stoics, but do we want

to? If we do not, we can expect to get little profit from just dipping here and there into the exercises described by the Yogis and Stoics, and carrying them out without having any clear aim in view.

Some years ago, a little book was published entitled *How to be a Yogi*. Perhaps if we followed its instructions for a sufficient number of years, we should all be able to become Yogis. But it is reasonable to ask first " Do I want to become a Yogi? "

For myself, I am perfectly clear about the answer. I do not at all want to be a Yogi. I have no ambition to be able to think about nothing, and I do not want to be free from desire. It would be convenient to be able to free myself from those desires which I cannot fulfil, but I am not willing to purchase this freedom at the cost of losing my enjoyment of food and drink, of the mountains and sea, and of losing my power of loving other persons. The Yogi may tell me that these desires bring sorrow to the person possessing them. That I know, and I judge that they are worth it. I do not, therefore, want to be a Yogi, and the mental exercises which would make me into one are of no use to me.

Every system in the past has had some definite aim, although these aims have differed widely. I suppose few of us could unreservedly accept the aims of the Yogis or of the Buddhists. More would be willing to accept the aims of Ignatius Loyola. It seems to be a peculiarity of our own times that we have books recommending us to practise mental exercises without any clear object at all.

I once bought a book on concentration which contained a series of instructions, one of which was to hold the image of a chair in the mind for as long as possible without allowing it to waver. At this point, the ordinary person very properly asks " Why? " and the author of the book gives him no answer. It is difficult to see why one should be better off through being able to think of a chair steadily for ten minutes or even for ten hours. Most of the thinking about chairs which any of us need to do in practice can be done quite effectively in ten seconds. What, then, is the object of this exercise? It is true that there are similar exercises in the Yogi systems, but these form an essential link in the ideal of attaining isolation from the world. Most

of us, however, would agree to reject this ideal.

The author may have known what was his object in this exercise, but certainly he did not explain it. Until he does, we may reasonably refuse to waste our time in concentrating on chairs. Exercises in concentration are, for many people, well worth carrying out, but it is more reasonable to practise concentration on some material worth while in itself—on some poem, for example, familiarity with which will be a permanent enrichment to the mind, or on the study of some branch of science, or even on the efficient performance of the task by which one earns one's living.

It should hardly be necessary to say that by mental methods one can only gain mental results. Physical results can only follow from physical means. Many writers and lecturers on this subject promise their followers wealth, perfect health, and beauty. But these are obviously external things which can only follow indirectly and in a very limited way from any process of mental development. Mental exercises may increase your desire for wealth and even your business efficiency, but if you are dependent for

your livelihood on inadequate wages or on the interest from shares in a worked-out gold mine, no amount of mental exercising will save you from being poor. Similarly it is childish and unscientific to look to mental methods to cure you of an ulcerated stomach or a hare-lip.

Mental methods may give you contentment with your physical limitations, they cannot remove them. It is true that the illness which results from fears and unsatisfied desires (and, no doubt, a great deal of illness is of this kind), and the ugliness which results from harbouring ugly thoughts may be cured by suitable mental exercises producing thoughts of health, confidence and benevolence. That, however, is all. There still remain economic conditions, bacteria, and physical disfigurements which must be fought by other methods. It is mere dishonesty when the pseudo-psychological writer wins disciples by promising them unbounded wealth, health and beauty, by means which can never alone be sufficient to win them.

We now come to the really important practical question. If we have decided to reject the ideals of the Yogis, and even of the Stoics—all stern ascetics who would

take away too much of the ordinary joy of living—what remains as a reasonable ideal for our mental development?

For the purpose of this book, I propose to take a very simple one—mental efficiency. Our minds are instruments with which we must work. We must be able to think accurately, to remember what is important and to forget what is trivial, to feel such emotions as will lead us to useful activities and to shut out those which are merely painful or useless; we must be able to sleep calmly at night as well as to think clearly by day; we must be able to judge correctly on disputed questions without being influenced by our prejudices or by unreasoning emotions, and we must have those dispositions of character which will lead us to conduct good in itself and serviceable to other people.

Perhaps I may be asked why I have chosen to take mental efficiency and not happiness as the goal to be aimed at in our mental development. Happiness may, at first sight, seem to be the obvious thing to pursue, but the wisdom of the past and the present unite in telling us that happiness is a quarry too elusive to be captured by direct pursuit.

There are two theories about the pursuit of happiness which are widely held. The first is the theory that the aim of all the activity of men is the winning of happiness; the second theory is that it ought to be. Sometimes both theories are upheld by the same people. These people believe that men, on the whole, do seek happiness and that they ought to, although they are often ignorant of the right way to find it.

I do not believe that either of these theories is true. Men seek other things than happiness, such as wealth or fame. They do not try to win these things because they think that they will bring them happiness, but because these seem to them to be ends attractive in themselves. Men may find more or less of happiness in the attainment of wealth, love or fame, or in the mere attempt to gain them, but it is a misunderstanding of human nature to suppose that men do not really want these things but only the happiness that they suppose will be the result of them. On the contrary, those who pursue such ends most ardently and most effectively will generally be found to be those who are least occupied with thoughts about happiness.

Indeed those who are always clamouring for happiness are not normal, but will generally be found to belong to the ranks of those ineffective people who have not satisfactorily adapted themselves to the demands of life. They are on a road which leads neither to happiness nor to efficiency. If a man is in pursuit of reasonable ends and pursues these in an efficient manner, he will be as happy as external circumstances and the peculiarities of his own disposition allow him to be. Mental efficiency may thus promote a man's happiness: the conscious pursuit of happiness will neither increase his mental efficiency nor, in the long run, his happiness.

This ideal of efficiency, if it is not so picturesque as the attainment of isolation by the destruction of desire, and not so seductive as the pursuit of happiness, will give us plenty to do.

Chapter II Auto-suggestion—Its Uses and Limitations

A METHOD of mental control which recommends itself because of its simplicity and its usefulness is the one called "auto-suggestion" or "self-suggestion." This is the method in which one tries to produce some change in one's mind by saying to oneself a form of words—sending oneself to sleep by saying "I am falling asleep," or trying to keep oneself from sea-sickness by repeating "I am enjoying this voyage and I am feeling fit and well."

This method of mental control is, in fact, very often successful. Undoubtedly it is more successful with some people than with others, and it is more successful in some tasks than in others. We may find ourselves able to send ourselves to sleep by auto-suggestion when there is no reason for staying awake except that we are in unaccustomed surroundings. We may, on the other hand, be much less successful when we are lying awake worrying about some ques-

tion of money, and quite unsuccessful if what is keeping us awake is a violent toothache. It may be worth while to mention at this point, that, if we do want to use auto-suggestion for sending ourselves to sleep when there is something like a worry or a pain which is keeping us awake, the best method is first to use a formula for the removal of the source of disturbance—one suggesting calmness or freedom from pain—and when that has been successful use the ordinary auto-suggestion for producing sleep.

One striking and quite useful thing for which the method of auto-suggestion may be employed is for waking ourselves up at a prescribed hour in the morning. If we wish to wake ourselves at some unusual time, it is sufficient to repeat to ourselves that we will wake up at that time, and we find that we do. Since waking up at a desired time cannot be done voluntarily in any more direct way, this is a very striking psychological experiment which should convince any sceptical person of the reality of auto-suggestion. Practically, however, I have found it open to two objections. First, if I rely on this method I find myself liable to

wake earlier than the prescribed time (sometimes more than once); secondly, on rare occasions (particularly when I am very tired) the method fails. It is, therefore, generally better in practice to rely on an alarm clock.

The most useful field of auto-suggestion will be found to lie in those activities in which neither a convenient piece of mechanism such as an alarm clock nor our ordinary powers of willed activity help us. Such, for example, are: going to sleep, getting rid of the slight but annoying conditions of depression or irritability which affect all of us at times, removing annoying thoughts which will intrude when we wish to be busy with something else, or overcoming the fear which assails us when we have to speak in public or when we find ourselves at a great height above the ground.

In any case our method of using auto-suggestion will be to frame a suitable formula to repeat to ourselves. "I shall cease to be disturbed by this thought and will be able to apply myself to my work easily and with concentration" would, for example, be a suitable formula against an obsessing thought or worry. "I shall speak boldly and well"

would be a suitable auto-suggestion against the fear of an audience. It should be couched in the form of confident assertion—not "I must" or "I hope to," but "I shall." Yet it should not be so absolute as to arouse in our minds an inevitable contradiction. "I am falling asleep" is a reasonable auto-suggestion against wakefulness, but "I am asleep" would be a plain and unconvincing lie which would probably fail in its object.

Having decided on a formula suitable for the particular auto-suggestion we wish to make, the next thing is to repeat the formula many times over to ourselves (let us say twenty times or more). The repetition should be with the mouth. The formula should either be said audibly or sub-vocally (with the lips moving but without making any sound); it should not be merely thought. M. Coué recommends that the formula should be gabbled, but it is possible that individuals differ in this respect. Many people find it more effective to repeat the formula in a deliberate manner as we should if we were making a confident statement to someone else. I should recommend that the formula be repeated many times, with movement of

the lips but without sound, and in a deliberate manner.

About the use of auto-suggestion for curing diseases, it is necessary to speak with a good deal of caution. Certain disease symptoms may be produced by the mind alone. These may range from simple headaches to conditions which to all outward appearance seem to be cases of serious bodily trouble such as kidney disease or rheumatoid arthritis. Of course, the person who produces all the symptoms of kidney disease, although his kidneys themselves are really in perfect working order, is not a mentally well person. He (or more probably she) is a victim of the mental disease of hysteria, which can simulate the symptoms of a large variety of physical disorders.

Since these symptoms have no real existence but are produced by the mind of the person suffering from them, it is reasonable to hope that they may be cured by mental means. But there are also genuine physical disorders which are not mentally caused and cannot be mentally cured. Because we read of cases of apparent paralytics cured by auto-suggestion under the influence of that talented exponent of auto-suggestion,

M. Coué, we must not jump to the conclusions that a true paralytic whose condition has been caused by the destruction of a trunk motor-nerve through injury or disease could have been similarly cured. It is quite certain that he could not.

No doubt there is a factor in the recovery from even physical diseases which is affected by our minds. We are more likely to recover from an illness if we feel confident of recovery, and in any case the bodily healing process itself may be aided by auto-suggestion. Auto-suggestions of confidence and returning health may profitably be used, but we must not rely on auto-suggestion for physical troubles when physical methods are necessary. We may use auto-suggestion to give us a confident attitude of mind and to assist the natural processes of healing even when we are suffering from a broken leg, but we must not allow our faith in auto-suggestion to make us neglect the services of a surgeon to set the leg. If we do, the results will be disastrous.

There are two dangers in the use of auto-suggestion for the cure of disease. First, there is the possibility that the habit of relying on auto-suggestion may be a danger-

ous one for the very persons who are prone to these "diseases of the imagination." One thing that is the matter with them is that their bodies too easily act out suggestions of illness received from their minds. When they try to cure themselves by auto-suggestion, they are accustoming their bodies still further to act out suggestions received in this mechanical way from their minds. In other words, they are strengthening by practice the very tendency which produced their illness. What they really need is often a mental discipline for strengthening their power of willed control, rather than a removal of their particular symptoms by auto-suggestion.

The second danger is that auto-suggestion may remove symptoms without removing their underlying physical causes. If a man suffers from toothache, he may succeed in removing the pain of it by auto-suggestion. But if he really has a decaying tooth, suggesting away the pain will not stop the tooth from decaying and it may make him neglect to go to the dentist. If he does not go to the dentist, he is no more sensible than the man in the ever-recurring joke about auto-suggestion who sits by his broken-down

motor-car and repeats the formula: "My car is working better and better." He is making the mistake of relying on mental methods to produce physical results.

Most of us, however, are sensible people and will not be guilty of such imbecilities. We will rely on mental methods only for the production of mental results, and we may use auto-suggestion in our illnesses with discretion and profit, not allowing it to take the place of physical methods when these are necessary. We may save ourselves from a sleepless night by auto-suggesting away the pain of toothache, but we will also resolve to visit the dentist the next day. Similarly we may use auto-suggestion to get rid of worrying thoughts about money which are disturbing our night's rest, but we will also resolve to reduce our expenditure until it is less than our income. Used in this way, auto-suggestion will be a useful mental medicine. Used in the other way it may be a dangerous drug.

There is another limitation of the use of auto-suggestion to which it is necessary to draw attention. This is that the method of auto-suggestion should not be used to take the place of the direct control of our actions

and thoughts which we call "willing." Willing is something so much more commonplace and familiar than auto-suggestion that we are likely to forget it when we are talking about methods of mental control. Yet the development of the power of willed control over our bodily and mental activities must not be forgotten in a scheme of mental development. In exploring the unusual methods of exercising mental control, we must not forget the commonplace ones.

The things that happen in ourselves—in our minds and bodies—are of three kinds. Some are automatic, such as the beating of our heart, the forgetting of the things that have happened to us in the past, and the healing of a bodily or mental wound. These are called "automatic" because they go on by themselves and we cannot in any direct way either help them or stop them. Opposite to these automatic activities are such things as striking a match, getting out of bed, or solving a puzzle. These are "willed" activities. Lastly, there is the kind of mental or bodily happening which is in between those two. These are happenings which are partly automatic but partly under our control. The action of breathing is a familiar

example. Our bodily and mental habits are important members of this class. Such things as the actions of shaving or the processes of thought and feeling which go on when we think along some familiar line (let us say, on politics) are mainly automatic, but we can attend to them by an effort of attention and control them if we want to.

A recent exponent of a system of mental control has put forward the aim that we should make all bodily habits into willed actions—that we should be fully conscious of and should have complete control of the movements made, for example, in sitting down in a chair. It is difficult to see what gain there would be in this. Our minds allow such movements to drop out of consciousness and to become automatic so that our conscious attention may be occupied with more important things. It is a general rule that processes of body which would not profit by our willed interference become automatic. It would be of no benefit to us to be able to control the beating of our hearts, and it would be a waste of time to try, although it is quite possible that we could learn to do it if we tried hard enough. When our automatic bodily processes are

going on quite well by themselves they are best left alone.

Now it is obvious that a great part of the working of our minds is similarly automatic. The general attitudes of our mind towards persons and things and towards its own processes and towards the processes of its body are all automatic—they go on by themselves without our conscious interference.

What we are trying to do in auto-suggestion is to get some control over those processes of our minds which commonly go on by themselves. It may be objected that we ought not to use auto-suggestion because it is best to leave the automatic actions of our mind to take care of themselves so long as they are working satisfactorily. There is much good sense in this objection. So long as the automatic activities of our minds are going on satisfactorily it is unwise to interfere with them by auto-suggestion or by any other method. Medicine should only be used when we are sick and not when our bodies are working properly. Auto-suggestion is a medicine of the mind and not a food.

I have just said that we can leave the

automatic activities of our minds to take care of themselves *so long as they are going on satisfactorily*. It is necessary to emphasise that condition. If we are lying awake in bed at night, if our minds are haunted by a worrying thought, or if we find ourselves unable to concentrate on a task which demands concentrated attention, then the automatic activities of our minds are not working to our satisfaction. If we cannot put right what is wrong by direct willing, then we shall be wise to use the method of auto-suggestion.

Let us be clear what is meant by " willing." It is something perfectly obvious and commonplace. If I move a finger because I choose to, or if I get up and walk to the door, or if I decide to start thinking about my summer holiday, these are all " willed " activities. They are things which would not have taken place if I had decided against them.

There is, however, another and wrong sense in which the word " willing " is used. I have an occult book which gives as an exercise for developing the " astral body " that one should sit in a chair and, with eyes closed, " will " oneself to be out of it. What

the author means is that one should think intensely of oneself as out of the chair. But this is not willing, it is merely a particular kind of wishing. If you sit in a chair and really will to get up, you get up. This is the evidence that you have willed to get up. You could only go on sitting in a chair and "willing" to be out if you were tied there, and even then you would make all the movements of straining against the ropes in your attempt to get up. Sitting in a chair and thinking strenuously of getting up without sending the necessary nervous impulses from the brain to the limbs whose movements would get you up is the most fatuous substitute for willing that can well be imagined. This is an obviously wrong use of the word "will." The sign that you "will" something is that you do it (unless forcibly prevented).

We have already seen that certain automatic happenings of our minds and bodies cannot be brought directly under our power of willing. There are a great many others, however, which can. Examples are such activities as walking, talking, thinking and remembering. Auto-suggestion should not be used for directing these willed activities.

For example, if we want to get out of bed on a cold morning, the right way to do it is to make a strenuous willed effort which gets us up, not to repeat to ourselves the formula : " I am just going to get out of bed." This is a part of our behaviour over which we have direct control and it is important not to lose this power of willed control. It is impossible to estimate the gain to us which results from the fact that we have a direct kind of control over our thinking and talking which we have not over our sleeping and the beating of our heart.

The power of willed control over thoughts and actions is a power of the mind which is, at least, as well worth cultivation and development as any other. The person who can do things simply because he chooses to do them (such as standing his ground when he is afraid, or stopping smoking when he wants to) has a more efficient mental apparatus than the person who can not. How are we to cultivate this power of willing? Like most other things it improves with practice and is weakened by neglect. It must be cultivated by constant exercise. William James recommended that we should all practise our power of willing by doing some-

thing we do not want to do every day simply for the sake of developing this side of our characters. Many persons, of course, have to do every day many things they strongly dislike. Such persons may face these necessary evils boldly and so develop their power of willing. Those, however, who lead easy lives may often have to make their opportunities for strenuous efforts of this kind.

Where we have this power of willed control over our bodily or mental processes, it should be developed and we should make no attempt to supplement it by the use of auto-suggestion. Auto-suggestion steps in as a method for gaining control over those processes which are automatic and therefore out of our direct control. For this purpose we shall find it a useful instrument.

Chapter III How Habits may be Formed and Broken

If I move my arm or one of my fingers in a new way, it is easier for me to make that same movement again. This is the first law of bodily habit. It states the well-known fact that movements improve and become easier by practice. Also we know that a new action is, at first, clearly present to our consciousness, and it is more under our control than it will ever be again. If we go on making this same movement, it becomes more and more automatic. It seems to go on by itself, and little effort is needed on our part. Instead we may find that an effort is required to stop ourselves from making the movement. The first carrying out of a new bodily or mental activity prepares, as it were, a track for its future happening so that it takes place more easily and more inevitably.

The final stage in this development is when actions constantly repeated seem to take care of themselves, and checking them by willed effort has become difficult or impossible.

They have then become *automatic.* If the activity is one which we want to carry out (such as the movements in a game), we say that we have acquired skill in it. If it is one that we do not want to carry out, we say that we have contracted a bad habit.

The same is true of mental habits. If I think a thought once, that thought more easily comes back. The more often I feel an emotion, the more easily will that emotion occur again. After a time, it may require an effort to stop myself from thinking a familiar thought in a familiar way. The stage in thought-habits corresponding to the automatic stage in bodily habits is when they become obvious, when they seem to think themselves and it seems impossible to doubt them. Such obvious habitual thoughts are, for example, that only one straight line can be drawn between two points, that our political opponents are stupid or wicked, and that two and two make four. Many other thoughts, even judgments about persons and things, have acquired this obviousness through habitual use. Yet these apparently obvious and certain judgments must very often be false, because the habitual

judgments of one man may be quite different from those of his neighbour. We cannot all be right about the things we feel certain of.

There is another law of bodily habit. If I repeat two movements together, or one after the other, then, whenever I afterwards perform one movement, the other is strongly inclined to accompany it or to follow it. In this way, we form groups or chains of habitual bodily movements. Such are to be found in shaving or in the complicated set of movements used in making a stroke in a game of skill. If we go on repeating them these groups of movements too become finally automatic. The movements made, for example, in opening a door become so familiar to us that we need only push our hand towards a door-knob and the rest of the necessary movements carry themselves out without our intervention and without our having any consciousness of them.

This again is also true of mental habits. Two or more thoughts or feelings which have occurred together more than once tend to occur together again. The laws by which they are grouped together are called the Laws of Mental Association. They are really laws of the formation of mental habits. For

example, if a child has frequently had the feeling of fear when he has seen a dog, the feeling of fear will be more and more strongly and finally perhaps inevitably called up by the sight of a dog. If a man has heard violent language and has felt angry feelings many times in connection with the members of a particular political party with which he does not agree, he finally forms a habit of thinking such violent thoughts and feeling angry emotions whenever he meets or thinks of members of this party. He has formed a mental habit of which he has more or less completely lost control. If, as is probable, the reproaches are unjust and the anger is unnecessary he has formed a mental habit which is thoroughly unserviceable. Such unserviceable mental habits are what we ordinarily call "unreasonable prejudices." This habit prevents its possessor from acting reasonably and from thinking calmly about a certain group of questions.

Unhappily, the man himself is probably not discontented with such emotional and intellectual habits. Many people (and even highly intelligent people) wear their social and political prejudices with as much satisfaction as if they were a row of medals.

Their satisfaction, however, does not alter the fact that these habits interfere with the usefulness of their mental processes. No scheme of mental control would, therefore, be adequate which did not attempt to remove such prejudices and to replace them by more serviceable habits of thought.

This tendency of our actions and thoughts to become more and more mechanical and so to elude our control seems to many people to be a depressing fact. Even William James suggests that in most of us, by the age of thirty, the character has set like plaster, and will never soften again. We seem to be like trams which lay their own tracks in the first place but which afterwards go on running in them with only occasional variations.

Some people are so depressed by this prospect that they are willing to adopt as a principle in their lives the attempt to break all the chains of their habits. Yet not all habit formation is objectionable. Much of it is essential in any efficient and well-ordered life. It is through the familiar everyday things such as shaving, sitting down, and mentally digesting the morning's news becoming automatic through habit, that we have energy and attention to devote to other

things. No man could develop a business or write a book or engage in any other activity requiring new action and new thought, if he still had to give to shaving or to writing his name the concentrated attention that was necessary when these were new actions. By having made these into habits he has time and energy to spare for other things.

For this reason, William James advised his readers to make all the details of their daily lives into habits, in order to avoid the waste of effort which results from having to think about them. Opposite to this is the practice of a recent teacher of mental control who is reported to have made a principle of breaking down all the pre-formed habits of his disciples, their times of eating, of going to bed, and so on.

Although these seem to be opposite ideals, a little reflection will show that there is a certain amount of sense in both. Ordinarily such things as eating, sleeping, etc., must be habits, but it is a great gain if we can at will break across these rigid ordinary habits of action and thought so that we can release ourselves from slavery to them. Then we shall be able to choose freely whether we are to retain them for the future or to form new ones.

This breaking across our ordinary habits is perhaps one of the mental advantages we gain from such a holiday as one in which we camp out, thus interfering with all our ordinary habits of eating, sleeping, sitting down, and so on. Even if such systematic interference with ordinary habits were made a feature of the discipline we imposed on ourselves in a course of mental control, it clearly could not be with the object of permanently freeing ourselves from all habits. As we have already seen, this would cause a tremendous waste of time and energy. The only reasonable aim in such a wholesale destruction of old habits is an attempt to get the mastery of them so that we can be free to choose which of them we are going to keep and which we are going to replace by new habits.

It is of no use simply to regret this tendency of our bodies, of our nervous systems, and of our minds, to form habits. We must accept it and make use of it. If this peculiarity of our bodily and mental make-up makes it more difficult for us to break off a bad habit, it also makes it easier for us to form a good one. If it is true that every time we (let us say) use bad language, it becomes easier for us to use bad language again, it is

also true that every time we control our tendency to use bad language by willed effort, it is easier to control it again. What it amounts to is that we must attempt to form the habits we want to form by repetition, and we must break the habits we want to break by never allowing them a repetition. We cannot choose to have no habits at all, but we can choose what habits we shall have. We must use the fact of habit formation as an ally in our attempt to gain mental control and not always treat it as an enemy.

The method of breaking a habit is simply by refusing, by willed effort, to allow it any repetition. Simple as this sounds, it may, of course, be a task of almost insuperable difficulty. There is no easy way of overcoming a deeply-rooted habit, although there are methods of lightening the difficulty. Suitable auto-suggestions may sometimes be used successfully to reduce the strength of the craving to return to a habit we have decided to abandon. Another way of making the process less hard is always to perform some other action when one feels the impulse to carry out the old habit. A simple example of this is, when trying to break oneself of smoking cigarettes, to put a small hard sweet

into one's mouth whenever one feels the craving to light a cigarette. In the same way, a student, let us say, struggling against a persistent habit may find that if he deliberately applies himself to his work every time he feels the impulse to his habit, the difficulty of resisting it will grow less and finally disappear.

When it is not a question of a simple bodily habit but of the much more complex situation of a drug habit, the difficulty may be very great. In attempting to cure a habit of drug-taking, it is not simply a habit of a few muscles that has to be broken, but one formed by the whole body and mind, a habit of the nervous system, of the digestive system, and so on. If the supply of drug is stopped, a physiological craving is set up which no effort of the mind can stop from being acutely painful even though willed effort may be successful in resisting its impulse.

In all cases of breaking a habit, the ideal is to permit no exception at all to the rule of not carrying out the habitual action in question, once the fight against it has started. This ideal rule cannot always be carried out strictly. In breaking the addiction to some

kinds of drug, for example, the bodily and mental disturbance which would result from a sudden stoppage of the drug may be so severe as to be dangerous. In these cases, the dose must be decreased gradually. The ideal rule of complete and absolute stoppage of the offending habit should, however, always be followed when it is possible.

Habits of thought and feeling also demand our attention. We form habits of always feeling anger at the mention of some persons or of the members of some nations; and we also form habits of feeling fear in some situations (as when children feel fear in the dark, some psycho-neurotic persons feel fear in all enclosed places, and most of us feel fear on heights). These are habits of feeling. Similarly there are habits of thought and speech, which determine what we shall believe and say about certain questions. The fact that we embrace a political or religious creed means that we have accepted certain habits of thought, so that on a certain number of new questions our minds are, in effect, already made up. When a line of thought becomes thoroughly habitual it appears to us to be self-evident or obvious, and we are surprised that it does not appear

to be so to other people, and we suspect them of being biassed and unreasonable. Yet the fact that a line of thought appears obvious may mean nothing except that we have thought it so often that it has become a mental habit. It is no guarantee that the thought is true.

Of course, mental habits, like bodily ones, have their use. They make us consistent. That, in itself, is a great gain practically. If we had no thought habits, our judgments would vary from day to day, and we might find ourselves on the platform of a prohibitionist league on one night and on the platform of a society supporting the liquor trade the next night. That would be a great inconvenience.

Also thought habits effect a great saving of mental energy. It is because we do not have to make up our minds afresh on every question that presents itself, that we have time and energy to spare for careful thought on other questions. A scientist would have little time or energy for thinking about the atomic theory if he had not made up his mind on thousands of other questions, such as the relative merits of Turkish and Virginian cigarettes, the prohibition question,

and the programmes of the three political parties.

The disadvantage of thought habits is that while they give us consistency and save us trouble, they may prevent us from acquiring new truth. Indeed, the breaking of old habits of thought is generally a condition which we have to fulfil in order to get nearer to the truth. The habit of thinking that the sun went round the earth was so deeply ingrained in men that it seemed to them to be an obvious truth which one would be a fool to deny until Copernicus shook himself free from this thought habit and showed that it was the earth which moved round the sun.

To come nearer to our own times, a lot of statements about space and time seemed obvious even to those who had thought most carefully about the subject (such as that the length of a rigid rod was always the same and could not be affected by the movement of the rod) until Einstein showed that nothing but long mental habit made these things appear obvious, for they were not exactly true. The difference, of course, was small enough not to be noticeable under ordinary conditions of observation. That was why we had formed the habit. But physicists were beginning to

study conditions under which the difference was important and were unable to make new conquests of scientific truth until Einstein had liberated them from their old habits of thought.

"To think accurately" was one of the aims we admitted as part of that state of mental efficiency which we agreed to regard as the aim of mental control. Thinking accurately must often mean an attempt to break down the obvious judgments which spring from thought habits. The habit of suspecting that our easiest judgments may rest on nothing more profound than our habits of thought should be one of the results of anything that can fairly be called a "liberal education."

One way in which this habit can be acquired is by consistently reading newspapers and books putting forward views with which we disagree. This might well be a piece of mental discipline for everyone desirous of keeping his mental processes under control. Mere unsympathetic reading with ejaculations of "nonsense," "rubbish," at every unwelcome suggestion will be useless. Our thought habits will not even begin to be broken down until we can read such papers

and books with sympathetic understanding, really entering into the new and unfamiliar thought of our opponent. Then we shall have started on the path of making a free choice in our opinions, and escaping from bondage to our old habits of thought.

In all attempts to overcome habits—habits of thought, of feeling, and of action—we must remember that it cannot be a reasonable aim to get rid of all habits. That would be to produce a condition of mind of hopeless inefficiency—a condition which we might describe as "mental anarchy." Our aim must be the more moderate but very important one of being able to choose freely which of our habits we are going to keep and which we are going to abandon.

IF, for the sake of a psychological experiment, you approach a gentleman sitting quietly in a tram and pull his beard, tweak his nose or call him a fool, you may notice that your experiment is followed by several interesting physiological and psychological changes. The rate of your subject's heart-beat will increase and the distension of the small veins in his skin will cause him to flush. The frontal muscles will pull down his eyebrows, causing the lines to appear between them which we call a frown. If you watch his upper lip closely you may notice a slight tendency of the corners of his mouth to rise. This is a relic of the snarl of the animals which attack with their powerful canine teeth. You may also notice a tendency of the hair at the back of the gentleman's head to raise itself and stand on end.

The most important bodily change, however (which may make the exact examination

of these other changes difficult), will be the impulse to violent behaviour. The subject of your experiment will either strike you, or at least will experience an impulse to strike, which is likely to be shown by a clenching of his fists. The striking, itself, may have its place taken by the use of violent and abusive language. At the same time, if you question your subject, you will find that he is experiencing an unpleasant feeling of peculiar quality which he will call "feeling angry." The whole condition to which you have reduced the gentleman is an example of a condition known as an emotion. It is the emotion of anger.

Another set of bodily and mental changes takes place when a man is strolling in a field and notices a bull approaching him in a threatening manner. The condition which the bull will produce under these circumstances is the emotion of fear.

A person under the influence of strong emotion tends to behave violently and in a manner which seems to show clearly to the onlookers that his body is, to some extent, like a machine out of control. While he behaves violently, such a man is unable to think clearly. This loss of clearness in

thinking may even make his behaviour less effective than it would have been if he were not under the influence of strong emotion. A boxer does not box best when he is angry. A really angry man may be less capable of making effective, stinging remarks to his opponent than if he had controlled his anger. Although fear makes it possible for one to run faster and harder than would have been possible in a normal condition, the uncontrolled and unreasoning way in which the frightened person runs may actually prevent his escape from danger.

The behaviour which results from strong emotion shows, then, a somewhat mechanical character. The man who is very much angry or afraid is rather like a motor-car over which the driver has no control. The emotions are, in fact, due to a very mechanical part of our nervous system. They are not results of the activity of the brain, which is the part of our nervous system that thinks and reflects and controls. They are not even started by the part of the nervous system to which the brain belongs. Emotions result from the action of a very primitive part of our nervous system called the autonomic nervous system. This is the system of which the solar plexus

is a part and which works in co-operation with certain of the glands, such as the thyroid gland.

It is because of this mechanical nature of the emotions that systems of mental culture have always had as part of their aim the control of emotions. Plato and Buddha, the Stoics and the exponents of New Thought, are all alike in trying to teach people ways of subjugating their emotions, although they have differed a good deal in how far they have wanted to destroy the emotions altogether. It appeared to these thinkers that a man acting under strong emotion was less of a man and more of a machine or a beast. Even if we confine ourselves to the simple aim of mental efficiency, we cannot be content to leave our emotions unregulated. Highly emotional behaviour is very generally highly inefficient behaviour.

There is an obvious difficulty in the control of the emotions which must strike us at once. There is an essential part of the emotions which is not under willed control at all. We cannot control the beating of our heart, or the blood supply to our skin, by any willed effort however great. At the same time, it seems certain that if these changes of our

skin and blood take place we shall feel emotion. If, for example, when we see a bull, the blood is driven from our skin, our heart beats faster, and our knees start trembling, then we shall feel fear. If the emotion of fear follows from something that we cannot control, in what possible manner can we control our fear?

The answer to this question takes us to the root of the psychological problem of controlling the emotions. It is perfectly true that there is a part of the emotion which we cannot directly control. It is also true, however, that there is a part we can control. This part is the bodily behaviour and the facial expression to which the emotion gives rise. While the frightened man cannot stop himself from turning pale, he can stop himself by willed effort from running away or from showing the expression of the emotion of fear in his face. Of course, in any particular case of fear, the impulse to run away and to show fear by the movements of the face may be so strong that the effort required to control them is greater than the person in question is capable of. They are, however, theoretically still controllable, and how far a man is actually able to control them depends not

only on how strong they are, but also on how far he has developed his capacity for willed effort. If he wants to master his fear, it is these controllable bodily changes that he will attack and, as he successfully controls them, both the involuntary bodily changes (such as the turning pale) and the unpleasant feeling itself will tend to disappear.

We may perform some simple experiments which will show us the influence of our bodily behaviour and expressions of face on our feelings. If you try drawing your eyebrows down in a frown and clenching your fists, you will begin to feel yourself experiencing an emotion of anger even although there is nothing to be angry about. If, on the other hand, when you have something to be angry about you make an effort to keep your forehead smooth and your hands open, the feeling of anger will grow less and will rapidly disappear altogether. In the same way, if you sit in a chair with your muscles relaxed, your head bowed down and your mouth drooping you will begin to feel depressed. If, when you are depressed about something, you brace up the muscles of your back, making your body erect, and pull your mouth into a smile you will find that the depression fades away.

The first principle, then, in the control of the emotions is this. While the feeling part of your emotion is not itself under willed control, the facial expression and the behaviour of the emotion can be controlled more or less. Whether less or more depends partly on the violence of the emotion at the moment, but partly also on the extent to which you have habitually practised control of these things. You cannot stop yourself by a direct effort from feeling afraid when, let us say, you get up for the first time to address an audience, but you can stop yourself from looking cowed and from running away, and success in overcoming these controllable parts of the emotion will tend to result in the feeling itself disappearing too.

Another useful principle in the control of the emotions is that reflective thought about the object causing emotion tends to make the emotion disappear. This was a principle which was well understood by the Roman Stoics and by the Buddhists. The Stoic Emperor Marcus Aurelius Antoninus reminded his readers that the expensive wine they sought after was nothing but moisture squeezed from a grape, and that the rich purple robes which filled them with pride

were nothing but sheep's hair twisted together and stained with the blood of a kind of periwinkle. The Buddhists were taught to go into graveyards and to reflect on the changes which the bodies underwent so that they might cease to desire the pleasures of a life which was nothing but a series of changes in similar bodies. An exactly similar idea lies behind the reflection, when some occurrence rouses an undesirable emotion, that "it will make no difference a hundred years hence." These are all examples of emotion being dissipated by reflection about the nature of the objects calling out emotion.

A very similar principle is to be found in the teaching of Jesus to his disciples that they should abolish worry from their minds by considering (that is, reflecting on) the birds and the flowers which were taken care of and clothed by God without any anxious care on their part.

A knowledge of psychology ought to provide us with an abundance of reflections to prevent us from being carried away with anger at the behaviour of another person. We can not only consider the nature of his impulses and feelings, but we can also reflect on the physiological character of our own

emotions. If the old gentleman with whom this chapter started had been a Stoic with some knowledge of modern psychology, he might have reflected in some such way as the following: "This young man who has just pulled my beard has done it under the influence of his instinct of curiosity. The result of his action has merely been a momentary tension of the hairs on my chin which has caused me only very slight and transitory discomfort and has had no other results either bad or good. Moreover, this emotion of anger which I feel is nothing but the echo in consciousness of a change in the blood supply to my skin and internal organs, and why should I, a free man, have my conduct dictated to me by the condition of my viscera?" Long before he got to the end of these reflections he would find there was little left of the powerful emotion of anger with which he had started.

Whatever method of subjugating undesirable emotions we put forward, we must be prepared to face one objection. This is the objection of the man who says that reflective thinking and the willed control of behaviour and expression are all very well for slight emotions, but they are powerless in the face of great ones. Our advice may be good

enough to save a man from painful worry when he has lost sixpence, but it is a useless remedy to offer him when he has lost the accumulated savings of his lifetime.

This is a real difficulty, although it is by no means fatal to the principles which have been suggested. It is true that no method of mental control can be used for the first time by a person while suffering under a great grief or while he is in terror or in a rage. The intensity of the emotion itself will effectually prevent him from either thinking calmly or controlling his muscles.

The practical conclusion to be drawn from this fact is that it is useless to wait until one is suffering from a very powerful emotion before beginning the practice of controlling emotions. One might as well start heavy weight lifting by starting at once on the heaviest weights without first having strengthened one's muscles on the lighter ones. The person who habitually controls his slighter emotional disturbances will find that he has developed the power to deal with his greater ones. It is the person who habitually gives way to painful worry over the loss of sixpence who is utterly overwhelmed by a more serious loss.

If we wish to be able to resist the painful and unserviceable emotions of grief, anger and fear, in serious crises, we should use all methods of control to resist them when they come in milder forms. We should, for example, make the habit of not worrying over a small loss of money or when we miss a train, of not allowing ourselves to give way to irritation when someone jostles us in a crowd, or to fear when a vehicle in which we are travelling narrowly escapes an accident. A distinguished general of conspicuous courage has confessed that he was led into the military career by the fact that he was so unusually timid that he was forced to be always practising the control of his fear until this control became a strong habit.

Our aim, however, cannot be to get rid of all emotions, for some emotions are desirable. The world would be much worse, for example, if all mothers and all lovers used psychological methods to get rid of their feelings of affection. The total destruction of all emotion has, as a matter of fact, sometimes been taught in the past as an aim, and other writers have taught the less extreme doctrine that all emotions should be moderate in amount.

Nor can we be content only with getting rid of undesirable emotions. This must be part of our aim; we must absolutely abolish from our lives all worry, all needless fears and anger against other persons. But this is not all. Other emotions are generally desirable. Such are, for example, pity and the sympathetic emotions generally, anger at evil things (such as disease, injustice and war) and the fear of what is really dangerous.

The methods we have described might, of course, be used to get rid of these desirable emotions as well, but the result would be to make our characters poorer and really less efficient. The light-minded person who manages not to be moved by sympathy or by indignation at real evils has a character we shall not wish to set up as an ideal.

The desirable emotions (or the habit of feeling emotions in situations in which they are desirable) can, in fact, be developed by the use of the same principle of cultivation by exercise as has already been described for the formation of good habits. They can also be cultivated by thought. Some parts of systems of meditation (such as those used by many religions) are attempts to use exercises of thought in order to cultivate desirable

emotional habits. We may, for example, cultivate the habit of feeling the sorrows of other persons as if they were our own, by making ourselves think of their sorrows until we feel the pain of them in ourselves. Or we may hold the picture of someone who has injured us in our mind, and force ourselves to think kindly of him.

I see no reason for doubting that meditation consistently carried out for long periods of time is a powerful method for attaching emotion to new objects, or for detaching it from other objects. Let us suppose that someone carries out Ignatius Loyola's meditation on Hell in accordance with its author's instruction, using all kinds of mental imagery to picture its horrors to himself, not allowing his efforts to stop until the end of an hour, and repeating the meditation the prescribed number of times. It seems reasonably certain that he will have in the end a much increased fear of hell.

To most of us the end attained does not seem a desirable one, but might the method not have been used for ends which the most modern mind would recognise as desirable? There are, of course, other meditations in Loyola's system with whose objects we should

all sympathise. Apart, however, from religious objects altogether, there are ends which might well be served by systematic meditation. The effectiveness with which we judge and act in many matters is impaired by the little emotion that is called out by important things remote from our experience and by the unduly great emotion called out by unimportant things closely affecting ourselves.

The modern man or woman's book of meditations might include an exercise of an hour each morning picturing the discomforts of life in a tenement. Imagery of sight and smell might call up the smoky chimney and the week's washing airing in the room in which supper is served, the husband too tired by his day's work and too dulled by its monotony to be kind; the bodily feelings might be pictured of the woman who had the full burden of the crowded and muddled home up to a few days before the birth of her baby, and so on. Another exercise might be one in which we meditated on our bank-balances as the Buddhists meditated on their bodies, until our emotional detachment from our possessions was so complete that we could judge with even and unbiassed

minds the desirability of legislation which would increase the income tax or of municipal action which would increase the rates.

Another reason why we cannot be content merely to try to get rid of all emotion is the fact that emotion is the great driving force to action. To abolish emotion would be like abolishing the steam from an engine. Without some degree of fear, we should not be sufficiently careful to avoid really dangerous things; without pity, we should not be sufficiently active in relieving distress; and without some measure of anger, we should not be sufficiently strenuous in fighting against evils. Our aim must be to be able to choose freely by what emotions we shall be influenced and what ones we shall reject. No emotions are, of course, desirable in all circumstances. The desirability of an emotion in any particular case, depends largely on the conduct it leads to. It is as important that a child should be taught to be afraid of a savage dog and of influenza germs, as that it should be taught not to be afraid of the dark.

Another point to be remembered is that while emotions may be serviceable to action they are always a hindrance to clear thinking.

We do not think clearly, logically and accurately when we are thinking in a state of anger or even when we are thinking in a state of tenderness. The reason why we make errors in our thinking is not, as the older philosophers used to suppose, because we are ignorant of the laws of logic, but because we think under the influence of emotion. I look forward to the day when it will be an offence punishable by a long term of imprisonment for a man to make a speech calling up strong emotions in people who have to make responsible decisions for which clear thought is necessary. I am thinking, for example, of such times as an election. The term of imprisonment would be no shorter for the sentimentalist who made his audience weep than for the master of invective who made them angry. Either should be imprisoned on a charge of having confused the thought processes of the electorate by inducing emotion.

If we wish to think correctly we must think, so far as we can, without emotion of any kind. When we have come to our decisions we can, of course, put all the emotion at our command into our subsequent actions. Calm thought must be the

condition under which we select the emotional impulses which shall drive us to action. Our ideal must be to think calmly and to act emotionally.

This does not mean, of course, that the orator has no useful social function. His task should be that of inducing emotion when action and not calm judgment are needed. This would be the opposite of our present unreasonable arrangement. Now, when we have to make responsible decisions on the rival merits of Free Trade and Protection or of privately owned and nationalised industries, instead of having a calm presentation of the observations, statistics, etc., from which alone a correct conclusion can be drawn, we hear fiery addresses calculated to activate our emotions and to make impossible a rational decision on the problems. When, on the other hand, it is necessary for us to be stirred into action about some admitted evil, like the prevalence of smoke in our large towns, we are given a closely reasoned address by a gentle, spectacled professor who illustrates his remarks by lantern slides showing figures and graphs. This would be the ideal form for an election address, just as our present election addresses would be the ideal

form for orations on smoke, sewage, microbes, or housing.

We must notice, too, how at the present time other methods of inducing emotion than oratory are also used often for the wrong ends. A kind of music, for example, which produces emotion and heightens activity is used by armies and to produce warlike emotions amongst civilians. War is not merely a useless but a highly undesirable way for civilised people to dissipate their energies, and if they have wars at all they should participate in them under conditions which allow them to realise to the full their sadness and futility.

There are, on the other hand, highly desirable activities, colourless and distasteful in themselves, which need the stimulation of martial music if they are to be carried out with enthusiasm. The day must come when dustmen and sanitary workers are led to their noble work by the music of the pipes and drums, and when they will point proudly to the medals on their breasts which were struck in commemoration of notable victories over dirt and disease.

WE cannot go far in the task of trying to regulate our emotions without discovering that we are up against a stiffer difficulty than we expected. Emotional behaviour checked in one direction has a trick of finding expression in some other direction. We may, for example, have successfully formed the habit of not giving way to violent behaviour or even to violent or reproachful language, and then find that we have formed a new habit of criticising and discussing the faults of our neighbours.

We may do this with the best (even with the most pious) intentions, but still it is criticising and fault-finding. In a moment of self-illumination, we may suddenly realise that the old tendency to hostile behaviour which belongs to the emotion of anger is coming out in a new direction.

It is rather as if we had discovered a persistent weed in the garden, and had just cut down the part of it which we could see

above the ground and had neglected the long tap-root running below the surface, and the result had been simply that the weed had sprouted again from a new point on the root. Or, it is as if we had noticed steam escaping from a leak in a boiler, and after carefully stopping up the leak had discovered that the result of our care was simply that the pressure of steam had increased until it had forced itself out at a new leak at another point.

The trouble has been that the emotion itself was only a surface effect of something lying deeper in our character. This something is a permanent, deep-rooted disposition to feel and behave in the ways belonging to the emotion—a disposition which is inborn, which is the result of the way our bodies and nervous systems are made up, and which is inherited from a long line of ancestors human and pre-human. This inherited disposition is what we call an " instinct."

Instincts are generally named after the kind of behaviour they produce. We speak of " the instinct of pugnacity " which gives rise to the emotion of anger and to violent or pugnacious behaviour, of the " instinct of flight " which gives rise to the emotion of

fear and to the behaviour of running away from danger, and the "sex-instinct" which gives rise to courting, mating and home-making, and to the emotion of tenderness or love.

The relationship of any emotion to its instinct is very like that of the weed to its tap-root or of the leak to the pressure of steam in the boiler. Cut off the head of the weed and not only will its tap-root not be killed, it will even be stimulated to increased activity. Stop up the leak in the boiler, and if the steam cannot find an outlet somewhere else it will blow up your boiler. In the same way, if you cut off all the obvious outlets of anger, your instinct of pugnacity may find new outlets in talking scandal or in deploring other people's sins. If external circumstances cut off a woman's opportunities of feeling the emotion of tenderness and carrying out its behaviour for children of her own, her maternal instinct may drive her to lavish tenderness on other things—perhaps on a cat or a parrot, perhaps more usefully on some of the multitude of children and other people who are in need of loving help.

This finding of a new outlet for the behaviour of an instinct may be called a

" deflection " of the instinct. Thus we may say that the unmarried woman showing unusual love for a domestic animal or for unfortunate persons is deflecting her maternal instinct to them. In using this word " deflection " we are suggesting the picture of a stream which can be deflected into one channel or another at will. That is as good a picture as any of the others we have used.

All such pictures are in danger of misleading us if we take them too seriously, but they are helpful to clearness of thought in psychology. It is best to use several different illustrations so that we may avoid being misled by any of them. Some things that are true of an instinct may, for example, not be true of a weed with a tap-root, but may be true of a leaking boiler or of a dammed-up stream. We must use our illustrations with discretion.

A deflection of an instinct may, of course, be a good thing, a bad thing, or neither bad nor good. If your cutting off of the ordinary outlets of anger leads you to write abusive anonymous letters, that will be thoroughly undesirable and it would have been better if you had let out your instinct of pugnacity

in the ordinary way. If it leads you to carry on a war of extermination against the slugs in your garden, that will be a deflection which is good or bad according to whether you look at it from the point of view of the garden or of the slugs. If it leads you to engage more actively in the war against disease, so that your anger is called out by the existence of preventable disease, and you do valuable research work on the origin of cancer, or give money for furthering cancer research, your deflection will undoubtedly be a very good thing. Your instinct of pugnacity will have been deflected into channels of high social usefulness.

It is usual to give a separate name to the kind of deflection of instinct which is socially desirable and to call it a "sublimation." Thus one would be said to be sublimating one's instinct of pugnacity in cancer-research, but not in writing anonymous letters. A single woman who adopted an orphan child would be said to be "sublimating" her maternal instinct, but not one who gave her tenderness to a tame parrot. If we want a parallel to sublimation in our pictorial analogies, we shall have to imagine that the leak having been stopped up in our boiler, the steam is led

to the piston so that its pressure disappears in doing useful work, or that the water of the dammed-up stream has been led to a water-wheel.

It was so common at one time for writers on psychology to neglect the existence of the instincts and to treat such emotional conditions as anger, fear, etc., as nothing but acquired habits, that the pendulum has now swung rather far the other way. Many writers suggest that all cutting off of the outlet of an instinct in one direction must necessarily mean that the same instinct will find an exactly equivalent outlet in some other direction. If this were altogether true, it would follow that reducing the number of times you lost your temper with other people must always be followed by a proportional increase of the anonymous letters you wrote or of the slugs you killed, or of energy you devoted to the discovery of the origin of cancer. Similarly it would follow that increasing the number of times you lost your temper would be followed by a proportional decrease in all these other activities.

It should be clear that this is an exaggeration of a true principle. While it is true

that if you cut off the head of a perennial weed, it will sprout again from the root, it is also true that if you go on cutting off the new heads, the root itself will be weakened and will finally die. It is the same with instincts. If you make a habit of giving way to violent anger, your whole capacity for violence and anger will increase. On the other hand, checking the expression of anger at various outlets will tend to weaken your capacity for pugnacity. It is not that the energy behind an instinct is indestructible, but only that it is much more easily deflected than destroyed. If we are dissatisfied with our present emotional dispositions (if, for example, we are always giving way to anger directed towards the persons around us) it is generally easier and more efficient to attempt a wise deflection than to aim at the total destruction of the instinct concerned.

No true psychological teaching about the nature of instinct lends support to the singularly fatuous doctrine that : " Human nature never changes." Even the instincts themselves (the general tendencies to anger, fear, love, etc.), although inborn and rooted in the constitution of our nervous and endocrine gland systems, are not quite unchangeable.

But much more amenable to our will to change them, are the particular things which we hate, or fear, or love. These are determined by emotional habits which are, as it were, built on the foundations of our instincts. These emotional habits (or " sentiments ") are of far more practical importance to us in our adult life than are the instincts on which they are founded. You will find generally that it is the possibility of controlling such emotional habits which people are concerned to deny when they repeat the formula that " human nature never changes."

In truth, we not only can but must control our emotional habits. We cannot choose to be born without the capacity for anger. The constitution of our nervous systems and of our endocrine glands has settled that for us. But we can choose whether we shall be angry at, let us say, the inhabitants of certain other European countries or at the fact that a considerable number of the children in our own country are not able to get enough to eat. In the same way, we can choose whether to be afraid of bogey-men or of tuberculosis germs.

The fact that it is easier to deflect an instinct into a new channel than it is to cut

it off altogether is not, however, the only reason why the wisest way to deal with an undesirable mode of expression of an instinct is to look for a desirable deflection. It has been shown that the origin of many of the illnesses which are popularly called "nervous" diseases is the condition of stress set up by allowing an instinct no outlet at all. Hysteria is an example of such a "nervous" complaint.

We know now that the word "nervous" in this connection is inaccurate. These complaints have nothing to do with the physical nerves—that is, with the slender grey fibres which carry impulses to and from the brain. They are failures of the mind or rather of the personality as a whole to adjust itself satisfactorily to a condition of mental stress. The scientific name for such a disorder is "psychoneurosis," and the persons suffering from these disorders are called "psychoneurotics." The condition of a psychoneurotic person resembles that of a steam engine when you have stopped up the leak without giving the steam access to the piston or any other method of escape. The pressure of the steam will go on increasing until the boiler blows up.

The ideal cure of the psychoneurotic is to give her (or him) some useful outlet for the bottled-up instincts. If a woman develops hysteria through the damming up of her sex-instinct, her symptoms will probably be relieved if the tenderness denied outlet in the normal channels of love for husband and children can be given to some other object. If, for example, she can give the self-sacrificing devotion of love to an adopted child or to some charitable cause, she will probably get better.

This cure will, in fact, generally not be so easy as it sounds. The hysteric is not merely a person who through external causes is not able to give love. There are also generally peculiarities in her character which prevent her from giving love, and no cure is possible until these peculiarities are to some extent overcome. Some of these peculiarities are probably inherited, while others have been acquired during her life-time and must be overcome by the special technical methods of psycho-analysis which can only be employed by a person (usually a doctor) with special training and qualifications.

It is not, however, with these disorders that we are now specially concerned. What

is of more practical importance to most of us is to bear in mind the fact that a satisfactory and socially allowable outlet for our instinctive tendencies is the best preventative of psychoneurosis for the mentally unstable and for the conditions of unhappiness and mental unrest which may be the result of the damming up (or repression) of instincts in the person of sound mind. Both idleness and unsatisfactory conditions of work are likely to be unfavourable to mental health, because in both the energies of the instincts may not be actively engaged in the business of living.

The remedy is not, of course, to give free rein to all the impulses of our instincts whether socially permitted or not. Although this is a popular misrepresentation of a certain side of modern psychological teaching, no psychologist or psychotherapist has ever taught anything so ridiculous. Apart from any moral objections, such an ideal would be quite impossible of realisation, for our different instincts would come into severe conflict with each other. You could not give way to all the violence dictated by your anger without a drastic repression of the impulses of your sympathy (which is just as instinctive as anger). There would there-

fore be psychological obstacles to your giving way freely to all the impulses of your instinct of pugnacity quite apart from the external difficulty that such conduct would quickly land you in prison.

The requirements of other people (who have as good a right to live their own lives as we have to live ours) and the requirements of the country's laws set limits to the ways in which our instincts can be allowed to express themselves. Each man's problem is so to dispose of his instincts within those limits that he achieves the maximum mental harmony (and consequently of mental efficiency and of happiness). Whenever, for some reason, he is unable to allow any instinct its normal satisfaction, or when for some reason this satisfaction must be delayed, he will try to find some way of deflecting it. Suitable deflections may be found in such activities as athletic sports, artistic or literary production, or perhaps some other form of work.

It must be remembered too that the condition under which painful (or even dangerous) mental stress is set up is not simply the damming up an instinctive line of behaviour; it is above all the damming up of

an instinct after the instinct has gained strength by indulgence. The pressure in a pipe carrying water may not be very great if the pipe is kept permanently closed at one end; if, however, you allow the water to flow through the pipe and then suddenly close it, you set up a state of pressure which may burst the pipe. In the same way, you are not likely to suffer from much mental stress through never giving way to anger, but if you freely indulge your anger and then try to stop it, mental stress may be set up which makes the finding of a suitable deflection for your instinct of pugnacity an urgent necessity. This is much more obviously true of the sex instinct.

Peculiarly fortunate, of course, is the man who can find a satisfactory channel of sublimation in the work by which he earns his living. It is a special difficulty of our industrial civilisation that so many people are engaged in work so dull and unconstructive as to make this impossible. You will remember the war-time story of a private soldier who was reported by his sergeant-major to the company officer because he was not putting his heart into his work. The officer's inquiry as to what the work was

received the reply that the man had to pick up pieces of paper with a pin stuck into the end of a stick. The man would have been poor indeed in his equipment of primitive instincts if he could have found a satisfactory channel of sublimation in such an activity. This is true also of too many of the tasks of peace time.

People sometimes ask what precisely must be done in order to sublimate an instinct. This is a reasonable and a very necessary question. Many of the extremely vague directions to "sublimate your instincts" with which one meets, are rather like telling a man to go to Jericho, without telling him what road he must start along and where he must turn to the right and where to the left. Detailed information of precisely what mental or bodily activities one is to carry out, is very generally omitted in references to "sublimation," and without such details general exhortations to sublimate are of little use.

This detailed advice must, of course, often be different for different individual cases. We can, however, give a few examples of the kind of thing it would be. Sometimes it is sufficient, when the natural outlet of an instinct is stopped, for the person concerned

simply to apply himself vigorously to some other activity. Thus a young man disappointed in love may find that when he applies himself to football or to the running of a boys' club, the pain of his disappointment lessens and that as it lessens there is an increasing amount of mental energy behind his play or his organisation of the club. Without much difficulty, he has effected a satisfactory sublimation.

Sometimes, however, more specific methods are required. I remember a tutor's advice to a student whose life and work were suffering from the disturbing effects of a love which could not by any possibility be satisfied. His advice was : " Whenever you feel yourself becoming sentimental about X. start applying yourself hard to your work." In the same way another person, whenever he felt his temper rising, instead of giving way to violent action or language against the person causing him annoyance, might go into the garden and kill slugs until the slaughter of slugs made his anger die down.

The final result of persistence in such behaviour would be that the emotional state of dissatisfaction (of love in the first case, and of anger in the second) would appear in con-

sciousness as an impulse to work and to kill slugs respectively. In the end the emotional strain would be completely removed by successful application to these activities. Then the sublimation would be complete.

Sometimes this end might be attained by thought instead of by action, but this, I think, would prove a less easy method. If, whenever you felt anger, you made yourself think ferociously of slugs, you would no doubt find in the end that your pugnacity was deflected into the slug-killing channel. Action, however, is to be preferred to thought when action is possible. Effective action, however, in the new direction is not always possible when the impulse wells up. If, for example, we found our anger rising at our neighbour in the middle of a dinner party, it would not be practicable to leave the table and go out to kill slugs in our host's garden. Thought in the new direction, on the other hand, is nearly always possible.

Perhaps the most important of all reasons why instincts should be deflected into socially desirable channels is that so much socially desirable work remains to be done, while so much mental energy which might be put into the doing of it is wasted in other

directions. It is difficult to imagine what good results might follow if a quarter of the anger wasted in war or in internal strife were directed against such evils as poverty, bad housing, disease, and smoke; or if a quarter of the tenderness wasted in misdirected sex-activity were directed towards the sick and the destitute. All this wasted energy might long ago have set human society on the road to a condition of social efficiency from which the avoidable miseries and injustices of the present order would appear like a bad dream.

LET us imagine a large public hall filled with people of all kinds. On a raised platform at the end of the hall stands one man—a lecturer or a political speaker. He is the one person in the hall who is in a prominent position. All the others are, from the point of view of the meeting, so unimportant as to be negligible, although they may, in other places and at other times, be much more important persons than the speaker. For the moment, however, the speaker alone dominates the hall. If any of the persons present were asked what was happening in the meeting at any moment, they would reply by describing what the speaker was saying or doing at the time, and not what the lady in the front row was saying to her neighbour or what the programme-seller was doing. In the meeting, the speaker alone matters and everyone else has sunk into a relatively insignificant position.

This is a picture of a mind in a condition

of "concentration." One outside object, one line of thought, or one task that is being performed, is alone occupying an important position in the mind. The multitude of other impressions from the outside world or of thoughts from the mind itself are kept in relative insignificance. They are not allowed to interfere with the one main thing with which the mind is occupied.

There may, for example, be many persons talking in a room. We can hear them all, but we can single out one conversation amongst the many and make it alone prominent in our minds. We say that we are "listening" to this one conversation which we have selected to concentrate on. It is not necessarily the loudest or even the most interesting. We have the power to take any of the sounds assailing our ears and give it this central position. In the same way, of all the objects of sight, we can choose to "watch" only one.

A public meeting of the kind we have described would clearly be the most efficient kind of gathering for most of the purposes for which people do meet together in public halls. Suppose now that we imagine a meeting of a very different kind at which

every member of the audience interrupted at will. Such a meeting will be very inefficient. The speaker will get on only slowly, and may not be able to deliver his lecture or speech at all.

This is a picture of the common condition of mind-wandering or distractibility. Some people are unable to concentrate because, as soon as they attempt to put one thought into the dominant position, other thoughts force their way into prominence, by their interest or by their mere insistence. Such a person is trying, let us say, to read a difficult book, but is unable to grasp its meaning because his mind is simultaneously repeating the words of a song he heard yesterday, considering whether to buy a new pair of boots, hoping that it will be fine to-morrow, picturing where he will go for a walk if it is, and wondering whether he forgot to wind up the clock in the front room last night.

This is a condition into which we all pass when we are suffering from mental fatigue through having already carried out as much concentrated mental effort as is good for us. Nature has many devices for preventing us from exhausting our brains. Some people always (and all of us sometimes) find, how-

ever, that the mere effort to begin to concentrate makes them pass into this condition of mind-wandering, even when there can be no question of mental fatigue. For people afflicted in this way, there is clear necessity for some kind of mental discipline which will increase their power of concentration.

Most systems of mental development do, in fact, attach a good deal of importance to concentration. Books on mental development sometimes have as their titles the one word "concentration." The various Yoga systems of the East used methods of meditation far more arduous than any we are ever likely to be tempted to carry out ourselves, at the end of which those who used them were able to hold one thought steadily in the mind without distraction.

We may remind ourselves of a general principle which we laid down in the first chapter of this book. It would be absurd to pursue concentration as an end in itself. If it is to be practised at all it must be because it can be justified by its contribution to mental efficiency. In what way is concentration necessary to mental efficiency?

The real practical reason why we want this power of concentration is because it is essential

in all kinds of learning, mental and muscular. If we want to learn a poem, or to learn what Einstein thinks about space and time, or to learn a new movement in a game, there is only one efficient way of doing it. That way is to have what is to be learnt in the focus of attention and all irrelevant and distracting things excluded from the mind.

There are some movements which we cannot learn to control simply because we cannot by any amount of effort bring them into the field of attention. The beating of the heart is an example. Breathing, on the other hand, can either be controlled or go on automatically, because we can at will bring the movements of breathing into the field of attention although they are ordinarily outside it. The movements of the muscles of the heart cannot be brought into consciousness in the same way. It seems to be theoretically possible that by a special training of the power of attention it could. The Hatha-Yogis of India claim that by their method of training the power of concentration, they can bring the beating of the heart under willed control. It seems very probable, and the only reason for regarding this fact as of no more than theoretical interest is that there

seems to be no practical advantage to be gained from controlling the beating of one's heart.

Similarly, an American professor has recently been showing how it is possible to teach people voluntarily to move their ears by bringing this group of muscles into the field of attention. Again this is of no practical value (although it is said to be an effective drawing-room trick). Its interest lies in the illustration of the principle that new muscular movements can be learned as soon as the movements of the muscles can be made the subject of concentrated attention. An important practical application of this principle is in the teaching of singing and of phonetics, when the pupil is taught to give his attention to and so to control previously unconscious movements of the tongue and larynx.

While the various tasks of learning require concentration, they are not the only purposes for which we require this attitude of mind. Any task which is being performed for the first time or that involves new problems can only be carried out efficiently if attention is concentrated on it. Without concentration, one could not play chess, or conduct a busi-

ness, or sustain an argument, or do any bit of hard efficient thinking. Inability to concentrate is, therefore, a serious loss, and the highly distractible persons whose minds wander whenever they try to get down to a task are suffering from serious mental inefficiency. We cannot be surprised at the prominent position which concentration takes in all systems which claim to teach methods of increasing mental powers.

We can hardly fail to notice that there are two very different processes by which the mind can pass to a condition of concentration on one thing. If you see a street accident, it will at once occupy the focus of attention and all other impressions of all kinds will fade into insignificance. Your attention will be concentrated on the accident. This concentration takes place in a very different way from the effort you make in learning something by heart. The first is spontaneous. The accident has concentrated your attention on it by its own interest; no effort of yours has been necessary. The concentration in learning by heart, on the other hand, is deliberate; it is the result of willed effort. Like all effort, the effort required to maintain deliberate concentration is fatiguing. If it

goes on for a long time we feel tired and our minds begin to wander.

It is an obvious advantage in learning that the concentration on the thing to be learned should be, as far as possible, spontaneous and effortless, because then the task of learning will be least fatiguing. It is the business of every teacher and of every writer to present his subject-matter in as interesting a way as possible, so that very little effort is necessary on the part of his hearers or readers for them to keep their mind concentrated on it.

Yet, as a matter of fact, very few indeed of the things that are worth learning are so interesting that attention is concentrated on to them quite spontaneously. A good many things that we want to learn and a good many of the tasks we want to perform are so uninteresting that a great deal of effort is required in order to keep the mind concentrated on them. No one would ever learn a new language or write a book, if he trusted entirely to the power of the interest of his task to attach his attention to it continually. He must, on the contrary, make himself carry out the task he has started by a sustained effort of deliberate attention.

Since some of our tasks must necessarily require effort in concentration, the power of willed concentration is one which must be developed if we are deficient in it. There is only one way in which this capacity can be developed, and that is the obvious one—by practice. This means that there is one very important exception to the rule that any learning task should be made as interesting as possible; this exception is when it is being learned not for its own sake, but as an exercise in concentration. This does not mean that in order to practise concentration, one should learn something useless or unpleasant. It is better to acquire the ability to concentrate by learning a poem by heart and so acquiring something of permanent value, or by carrying out an operation delightful in itself (such as chess or draughts).

The Buddhists increase their powers of concentration by a discipline of continually holding the image of some indifferent object (such as a lump of clay) steadily in the mind until it can think of that alone. In the same way, children used to be taught by heart the names of the capes round the coast of England (perhaps they are still). This was clearly an exercise in concentration, since the

matter learned was of no value in itself. If the children, when grown up, ever wanted to navigate the coast of England, it would be necessary for them to buy a reliable chart and not trust to their memories. I have already mentioned one writer on mind-training who invites his readers to hold the image of a chair steadily in their minds for a long time.

We shall be right to follow the Buddhists and the educators, and the gentleman of the chair, in using deliberate practice as a method of improving the power to concentrate and of eliminating mind-wandering. We shall be wise, however, to modify their methods by remembering that concentration may as well be practised on something useful as on something useless. It will be better to learn poems by heart, to study mathematics, or to master a new language, than to burden our memories with the capes round the coast of England, or with the images of chairs. A practical exercise for those who find themselves deficient in the ability to concentrate would be to learn a certain number of lines of poetry every day.

There are a few points about the connection of bodily posture with concentration

which are worth noticing. A position in which the muscles are braced up is one favourable to concentration. If we are to do a job demanding real concentrated attention, we shall be better able to accomplish it sitting in a hard-backed chair than lounging in an arm-chair.

At the same time, it must be remembered that keeping the muscles tense is not the same thing as mental concentration and is not even essential to it, and it has the objection that it is fatiguing in itself. Many people think they are concentrating when they are really doing nothing except keeping many of their bodily muscles, such as those of the forehead and face, in a state of uselessly fatiguing contraction. This muscular contraction (which is very obvious amongst children and people unaccustomed to mental work) ought to be eliminated because it is unnecessarily tiring. Mental concentration can be carried on perfectly efficiently with muscles relaxed. Some great thinkers, as, for example, Descartes, have managed to work very efficiently in bed.

Different people differ very much in their power of quickly taking up an attitude of concentrated attention and of returning to it

when it has been disturbed by the necessity of breaking off one task for a short time in order to attend to another. Working with frequent interruptions can never be a very efficient way of carrying out concentrated work, but since all of us must sometimes attend to other things during periods when we wish to work, the power of rapidly reassuming the attitude of concentration after interruption is also worth cultivating.

Much more important is the power of concentrating in the presence of outside distractions. It is quite possible to concentrate efficiently while a great deal of noise is going on, even the noise of other persons talking, so long as no one talks to you. Experiment shows, in fact, that concentrated learning may be more efficient in the presence of outside noise, presumably because the presence of a possible source of distraction forces us to make a greater effort of concentration. The mental worker who insists that he can only read or write in a house which is absolutely quiet is a great nuisance to other people, and should realise that he is merely giving evidence of an inefficient and imperfectly trained mind. If he cannot concentrate in the presence of noises

which do not concern him, he should learn to do so as soon as he can.

We must never forget that concentration is not the only useful attitude of attention. It is useful for some things, but bad for others. Sometimes an attitude of mind is required in which more things than one are maintained in an important position of the mind. This is necessary, for example, when you are driving a motor-car or crossing the street. For these tasks, a concentrated attention would be just as dangerous as a condition of pure mind-wandering. The attitude required is that of "distributed attention."

Distributed attention may be compared to a kind of public gathering in which the platform is occupied by many persons acting together—let us say an orchestra, or a group of actors performing a play. There is still a platform and the arrangement of persons on it is not haphazard, but the platform is no longer occupied by one person. Indeed any one person on the platform who pushes himself into a too prominent position will spoil the effectiveness of the whole group.

We all know the kind of driver of a motor-car who applies concentrated attention to his

task. He keeps his eyes fixed rigidly on the part of the road immediately in front of him and grips his steering handle hard. If a chicken appears on the road a hundred yards ahead, that chicken becomes firmly fixed in the focus of his attention, while he ignores pedestrians on his left, the cyclists in front of him, and the motor lorry bearing down on him from a side road. Nothing but luck saves him from a serious accident every time he takes his car out. He generally considers himself a careful driver, but he is in reality a very bad one. He is bringing concentrated attention to bear on a task which can only be efficiently performed by distributed attention.

A similar distribution of attention is necessary when one is crossing a crowded road. The motor-car approaching on one side must not so occupy the mind that all the other possible dangers of the road are ignored. All must have their place on the platform of attention.

A person who uses concentrated attention for driving a car or for crossing a road is using his mind as inefficiently as the man who tries to solve a problem or learn a poem with distributed attention, and, on the whole, the results of the former mistake are likely to be

the more serious. It is worse to be run over than to fail to learn a poem.

In order to have our powers of attention efficiently under control, it is not, however, enough simply to cultivate the power of being able to concentrate and to distribute our attention. There is also a condition of attention which is the exact opposite of concentration—that of mental relaxation. This is when no effort is made to keep any impressions in the position of honour, but in which all have an equal liberty to force themselves to the forefront of our minds.

Is this to be regarded simply as a condition of mental inefficiency, or has it a value of its own? Undoubtedly, it too has its value in the right place. It is of no use for any kind of work, but it has value for rest. This condition of relaxed attention reaches its culminating point in sleep, when impressions from outside things are ignored altogether or merely woven into the fabric of our dreams.

We have compared the concentrated mind to a meeting addressed by one man, and the mind in distributed attention to the performance of a play. A mind in relaxed attention would be like a purely social gathering. In such a gathering everyone has equal rights,

but the whole character of the gathering is destroyed as soon as one person pushes himself to the front or talks in such a loud voice that he attracts the notice of everyone. Such gatherings can hardly have the ordinary criteria of efficiency applied to them. They are pleasant enough recreations, but they are not meant to be meetings to perform any work.

The power of relaxation also deserves to be cultivated. We cannot work all the time. The efficient worker is the man who, when his task is over, can leave his mind free to occupy itself as it will. The man who still thinks of his work when his work is over is like a spring which is always under tension. He is not a really efficient mental worker.

Probably the main reason for the use of alcohol by moderate drinkers is that it enables them to accomplish this end of relaxation. The experiments which prove that one works less efficiently mentally and physically after taking alcohol, always seem to me to be irrelevant to the real point. Certainly alcohol reduces efficiency in work, and this is always recognised by mental workers although not always by physical workers. It interferes with work just be-

cause it accomplishes this end of relaxation. Its justification (if it has any) must be sought in its value for the promotion of the relaxed attitude of mind. Its service is to rest, not to work.

I am not, of course, defending the use of alcohol but merely pointing out why it is used. It must be admitted that although alcohol helps relaxation, it has many bad effects. In any case, we do not want to be dependent on a drug for effective relaxation. If we have so cultivated our mental powers that we can relax at will, we are better off than the man who is dependent on his wine. Besides, the willed control of relaxation is cheaper.

If we want to develop the power of relaxing mental tension at will, this too can be made into a mental exercise which can be carried out at intervals between mental work. It will be an advantage, as we have already seen, to relax the muscles of our bodies, since this in itself has a tendency to induce the condition of mental relaxation. This may be done in a comfortable chair. While relaxing the muscles deliberately relax the tension of the mind. With as little effort as possible refuse to allow it to be engrossed by fatiguing

problems which are the subjects of its activity while it is at work. Allow it to occupy itself restfully with the day-dreams that will come to you. These dreams, like alcohol, have no value for work, but they have value for rest. By practising deliberate relaxation in this way, the power of relaxing at will can be brought under willed control. The man who has achieved this control can rest efficiently as well as work efficiently.

For efficiency in mental work, the ability to concentrate is undoubtedly of the very first importance, and it is an ability which can be improved by deliberate practice. Nobody doubts the value of concentration, even though not everyone is willing to make the effort necessary to escape from inefficient habits of mind-wandering in mental work. The danger is rather that we should make a fetish of concentration. The really efficient mind is the mind that can not only concentrate, but can also distribute attention for tasks demanding distributed attention and can relax efficiently when its tasks are over.

IT sometimes happens that when one is travelling in a railway train, one finds oneself sitting opposite to a dignified gentleman who obviously holds some administrative position in the public services. He puts down his paper, and begins to address one in such terms as these: "Perfectly scandalous, these miners. Wanting a seven-hour day indeed! I wish I could have a seven-hour day. I frequently have to work for fourteen hours or more in the day."

The psychologist might reply as follows: "Let us suppose that what you are saying is strictly accurate, and that you do frequently work for fourteen hours a day or more. There are two alternatives. Either these long hours of work are your fault, or they are not. If they are not, I am sorry for you. If, on the other hand, they are your fault, you ought to be ashamed of admitting that you are guilty of such a very inefficient method of working.

" For at least the last six of those fourteen hours you must be working in a condition of extreme fatigue, a condition in which not only is the work very unpleasant for you, but it is very badly performed. No doubt your temper during those last six hours is abominable, and both your subordinates and your wife are made to suffer by it. You work slowly and find that much of the work that is done one day will have to be done again the next. When you go to bed you are so tired you cannot sleep properly. You therefore go to your office the next morning even more fatigued than the day before, and this condition gets worse until finally your health breaks down.

" Although you may not be willing to admit it even to yourself, you probably take a certain pride in having broken down through over-work. When you tell people the cause of your illness there is a ring in your voice which suggests that you are thanking God that you are not as other men, even as these miners. You go away for a long and expensive holiday and come back at the end of a few months and start the process over again.

" It is possible that it is not your fault,

so I give you my sympathy, but in any case your satisfaction in the process is entirely misplaced. Avoidable indulgence in the poisonous products of over-fatigue is no more creditable than over-indulgence in strong drink. You would not be proud to say that you had performed your work in your office inefficiently and had finally had to take a long holiday because you had been drinking too much. You should feel no more satisfaction in the same result having followed from the fact that you have worked too much."

In this matter of work and rest we might all of us take a lesson from some of the most indefatigable and efficient workers that we can ever meet with, the muscles of our heart. Unless we are foolish and impose a severe, continuous strain on these muscles we find that they do not over-work themselves. They contract, driving the blood through the arteries and veins, and after each contraction there is a small fraction of time during which they rest. This rest period is just long enough for them to get rid of the fatigue which has resulted from their previous contraction and so enables them to contract efficiently again. If your heart muscles de-

cided to take a long rest because they had over-worked themselves, you would die. You would not think that your heart had done something to be proud of. There is no likelihood of this happening, however. The heart muscles of ordinary healthy people are not so foolish.

Let us be clear about the fact that over-work, whether thrust on us from outside or carried out by our own choice, is inefficient. Manual workers were severely over-worked in the early part of the nineteenth century in England, when even little children were working for fourteen and more hours a day. This system was not only brutal; it was also uneconomic. When a bill was introduced into parliament to shorten the workers' day from fourteen hours to twelve hours, the manufacturers cried out that all their profits would be lost because they needed twelve hours' work from their employees in order to pay the costs of production and on the last two hours alone they made profits.

It was found, however, that you do not reduce output by decreasing hours of work from fourteen to twelve. Such a decrease of hours may be followed (not immediately but in a short time) by an actual increase

in the amount of work done every day. In the same way, it has been found that the actual output of work may be increased by reducing hours of work from twelve to ten and even from ten to eight. Of course, this process cannot go on indefinitely. If the number of hours worked in a day is sufficiently reduced a time comes when further reduction of hours will cause a reduction in output of work.

To many people it seems as obvious as it did to the nineteenth-century manufacturers that more work will be done in a working day of fourteen hours than in one of twelve, while the opposite assertion seems to them to be absurd. Yet a little reflection will show that this proposition is less obvious than appears at first sight. No motorist supposes that he will get a greater mileage out of a gallon of petrol by spreading its consumption over three hours instead of two. In fact he will probably get less.

We are inclined to think of a man's output of work as a stream which flows at a constant rate, so we can get twice as much of it by tapping it for double the time. But suppose it were really a constant total amount each day, this would no longer be

true. Taking it out for double the time would mean that we got the same quantity at half the speed, and there might be secondary bad effects of this which would actually reduce the total amount. A dairyman is not fool enough to suppose that he could get an indefinitely large quantity of milk by milking his cows all day long, instead of only at the usual times.

The fact that a reduction of excessive hours of work may be followed by an increase of work performed is one that has been established again and again by careful observation. The reason is really a perfectly simple one. Let us suppose that a man is working for eight hours every day. While he is at work, fatigue is gradually set up by the accumulation in his blood of the chemical substances produced by his muscles while they are at work. During his night's rest these substances disappear and he gets up in the morning fresh and unfatigued.

Now let us suppose that his hours of work are suddenly changed to ten hours a day. He will start his first ten-hour day perfectly fresh and may therefore do as much work during the first eight hours of those ten as he previously did in the previous eight-hour

day, and what he does in the next two hours (which will be nearly but not quite a quarter of his previous work) will produce an increase of output. It might, therefore, be imagined that increasing his hours of work has increased his output.

So it has for the time, but at the end of ten hours' work he is much more fatigued than he used to be at the end of his eight-hour day. Since we supposed that his night's rest was just enough to overcome his fatigue from an eight-hour day, it will be insufficient to overcome his fatigue from a ten-hour day. He will start his next day's work still in a slightly fatigued condition, and his rate of work will, therefore, be slower through the whole day. His second ten-hour day will, therefore, produce a smaller increase of output than his first (and perhaps none at all). It will also leave him even more tired at the end than he was the day before. His night's rest will be still more inadequate to remove this tiredness, and he will start his third day more tired than he started his second, so that his rate of work will be still slower.

This process will go on until his rate of work is so slow during the whole day that his actual output through the ten-hour day

will be less than that of the eight-hour day. At the same time he will always be more tired and, therefore, less happy at his work, more liable to accidents, and producing more spoiled work.

If, in the same way, you now shorten his day's work to eight hours, his recovery will not be a sudden one. His first eight-hour day will start with the fatigue left by his previous ten-hour days, so his output for that day must necessarily be less than it was during the previous day when he worked for ten hours. There will be, to begin with, a fall in output as a result of decreasing his hours of work, but this again is only for a time. As he recovers from the condition of chronic fatigue which has resulted from his over-work, his rate of work will increase until during the eight-hour day he is actually able to produce more than he previously could in his ten-hour day.

I am, of course, only taking eight and ten hours as examples. The actual number of hours' work which will just be compensated for by a night's rest will depend on the nature of the work. Also, I am not suggesting that workers should be required to work until they can just recover from the effects

of their work by a night's rest. The worker may reasonably say that he does not want to devote the last ounce of his energy to his daily labour; and that in a prosperous country one of the social goods that we should aim at is a working day which is short enough to make it possible for the workers to devote time and energy to interests outside their work.

What has been discovered about efficient hours of labour in the workshop may very well be applied in the direction of our own studies or other activities in which we can choose our own times of work. The length of the most efficient working day is, of course, different for different tasks. A man might paint spots on a rocking-horse for a much longer day than he could carry bars of pig-iron. An eight-hour day has been found to be too long for maximum output in some parts of the very delicate work of scientific instrument makers.

Five hours is probably as long as can be spent profitably in one day in pure study. Students spend much longer than this in study just before their examinations, but it is most likely that what is read after five hours of work is not effectively retained.

One whose work is only partly study, while he is also engaged in administrative duties and a certain amount of office routine, may work for many hours longer without any loss of efficiency.

School children are given home-work which, with their hours in school, gives them a total length of hours of study longer even than an adult would find it possible to engage in intellectual work. If we suggest that school hours should be reduced, we are suspected of wishing to encourage idleness. The child, of course, does not break down. His protective mechanism against over-fatigue prevents him from paying concentrated attention during these long hours. The care of foolish adults to protect him from the dangers of idleness, produces, therefore, the very habit of inattentiveness and mind-wandering during intellectual work which will be a curse to him in all his later intellectual efforts. It is also liable to have the unfortunate effect of producing a distaste for study.

It will be only the very foolish who will misunderstand what has been said here, so much as to suppose that it is in praise of idleness. Idleness, or the failure to put into

our work all the physical and mental energy we can, is so obviously a source of inefficiency that it is hardly necessary to call attention to its evils. Those who are habitually idle are idle through moral weakness and not because they suppose it an efficient thing to be.

Nor am I suggesting that we ought to stop work when we feel tired. The feeling of tiredness can easily arise when there is no real fatigue, and may only mean that we are not interested in our work. One of the temptations of mental work is to stop not when we are fatigued but when we begin to be bored. Boredom may feel very much like fatigue; it may produce headache, mind-wandering, etc. The difference is that boredom can and must be overcome by strenuous willed effort.

Over-work does not mean working when you are fatigued. That is often done in sports without any harm resulting to the person whose heart is sound. The mountain climber is often in a condition of physical exhaustion, which would be a great evil if it were the permanent condition in which he did his daily work. On the mountains it is no evil, but is a valuable training for

character. The ability to endure fatigue, hunger and cold in the pursuit of sport is a safeguard against the development of that softness of character of which idleness is one symptom.

Over-work does not mean working when you are fatigued; it means habitually working more than your night's rest enables you to recover from. That is a much more complicated thing. Public men (bishops and statesmen) are fond of telling us that hard work is a good thing. That is undoubtedly true. They go on to say that no man has ever been harmed by over-work. That is a deadly lie. The very same public men who preach the glories of over-work preach a more edifying sermon when they themselves break down in health and take several months' holiday as a result of their inefficient habit of working too long.

It is impossible to guess how many wars and strikes have been precipitated through statesmen coming to responsible decisions when they are in the condition of irritability brought about by over-fatigue. In a national crisis the patriotic statesman gladly sacrifices his own night's sleep so that he may spend the whole night in conferences and negotia-

tions. Then on the following day there is a sudden rupture which to the outside observer bears all the marks of unreasoning bad temper on both sides due to nervous exhaustion. The patriotic statesman would be ashamed to sleep when the affairs of the nation required his unceasing vigilance, but it would often be better for the nation if he did.

It is true, of course, that circumstances may arise in which over-work is necessary. The public men who have broken down in health through over-work, have often done it through no fault of their own. Their only fault is the speeches they have made in praise of excessive work. Whether it be necessary or not, however, nature sternly exacts her penalty for over-work. For a sufficiently good cause we must be prepared to pay that penalty, but let us make no mistake about what the penalty is. Spending too long hours at work decreases, in the long run, the total amount of work we do. For every hour of over-work we must afterwards pay in compulsory rest far more hours than we have gained. The net result at the end will be a loss of work and not a gain. In order to work efficiently, we must also rest efficiently.

Resting does not, of course, necessarily mean remaining still. The brain worker who digs his garden in the evening may be resting more efficiently than he would by simply doing nothing at all. We are all resting by changing our kind of occupation when we take holidays, although our lives may then be full of strenuous and varied activities.

Of all methods of resting, however, the most important is sleep. No one can work efficiently who is suffering from sleeplessness. Sleeplessness may, of course, proceed from something which it is beyond the power of mental control to remove. If we suffer from sleeplessness as a result of indigestion, the remedy does not lie in the direction of mental exercises. The remedy is to stop eating indigestible things at supper. Similarly if we are kept awake by toothache, we must go to a dentist and have the tooth removed.

These are physical causes of sleeplessness, which must be treated by physical means. Sleeplessness may, however, have mental causes, such as worry, excitement, or even a simple conviction that one will not sleep.

Worry which is keeping one awake may, of course, have an outside cause. A man

may be kept awake at night because he is worrying at the thought that he is not able to make enough money to pay the expenses of his house. The sleeplessness itself may be making it more difficult for him to meet his expenses because it decreases his earning power. The important thing for him to remember, however, is that it is not his approaching bankruptcy that keeps him awake, but his anxiety about it. His sleeplessness has really a mental and not a physical cause; it is of a kind that will yield to mental treatment.

It is with the removal of such mental causes of sleeplessness that we are specially concerned. We have already mentioned in an earlier chapter the use of auto-suggestion to produce sleep. This is one of the most important practical uses of the method of auto-suggestion. Continual repetition of the formula " I am falling asleep " will be found to induce sleep when all such methods as counting imaginary sheep jumping over hedges are found to be quite useless. If, however, we are strongly excited or anxious it is better to use auto-suggestion first to produce calm and afterwards use it to produce sleep.

It is a peculiarity of sleep that it takes

place easily only under accustomed circumstances. Most of us habitually go to bed and turn out the light and surround ourselves by quiet before sleeping and we are likely to find that we are unable to sleep if any of these conditions are not fulfilled. These conditions can be summed up as the absence of stimulation from outside. We sleep on comfortable beds so that we may not have sensations of pressure on the muscles and bones which we should feel if we slept on hard boards. We turn out the light so that our eyes may not be assailed by visual impressions, and we insist on quiet so that our ears may not be disturbed by auditory impressions.

In fact, however, this absence of stimulation from outside is not so necessary as is commonly supposed. It is quite possible to sleep comfortably on a hard board with lights burning and noises going on all round. Most of us did so many times during the war. It is a useful power to have even in peace time, for there are few of us who do not sometime want to sleep in a train, or in a room with other people, when we shall be neither in physical comfort nor in silence and darkness.

The development of this power is not difficult. What keeps us awake is not the outside light or noise, but our own action about it. It is for this reason that we are aroused at once by a question addressed to ourselves, while we can sleep calmly through the much louder noise of a train in which we are travelling. The reason we are kept awake by a conversation or other noise in the room in which we want to sleep is generally that we are trying to do something about it—we are trying to shut it out from our consciousness.

This suggests what is the true remedy for the disturbance of sleep from outside stimulations. Do not make the effort to shut them out from your mind, but passively allow them to make their entrance. If you try to exclude the noise of someone else talking while you are trying to sleep you will find that you succeed only in keeping yourself awake. If, on the other hand, you listen calmly to the conversation, it will lull you to sleep. This is the surprising fact which has been discovered by everyone who has solved the problem of sleeping through outside disturbances.

I REMEMBER once reading a story about the examination of candidates for admission to a cadet college either of the army or navy. The boys were left in an ante-room before they went in for their final interview. At this interview, they were asked what objects were standing on the mantelpiece in the room they had just left. If they could answer correctly they were given high credit for their powers of observation.

This story illustrates a very common fallacy about memory. The person who devised this test obviously thought that there was some merit in remembering, quite apart from whether the things remembered were important or trivial. But this is absurd. None of us can possibly remember all the objects which meet us during the course of a day, and the mind that did so would have accomplished nothing useful, but merely cluttered itself up with useless memories. Our power of remembering is useful to us,

because it enables us to recall things whose recall will be serviceable to us. For this end, it is just as important that we should forget the trivial as that we should remember the important.

Most of us have in our houses a room which we use for papers, boxes, unseasonable clothes, and so on. What should we think of a man who put in his box-room everything that entered his house and destroyed nothing? We should not consider that he had a highly efficient box-room, because it would be so full of articles that were useless that its owner would be unable to find things when he really wanted them. It is the same with the mind. The well-ordered mind is the mind which remembers what it wants to remember and forgets what it has no need for remembering.

In all the useful remembering we do in our adult lives, this kind of selection is made. We just remember what we need and forget the rest. When I wrote the story with which this chapter begins, I had forgotten (and have still forgotten) the name of the newspaper from which I read it, the time at which I read it, the name of the college of which it was told, and the name of the

writer who told it. All these were useless details. I had just remembered the one thing that I wanted, which was the story itself.

That, surely, is a more useful, as well as a more usual, way of remembering than that of the person who recalls the ornaments on a mantelpiece. When we read books (certainly if we read a large number) it is very necessary that we should forget a great part of them. No harm is done by this so long as we remember all that we shall afterwards need.

As a matter of fact, we are not at all likely to find ourselves burdened with this kind of gramophonic memory which forgets nothing. Our forgetting of the unimportant takes place automatically and efficiently and may, therefore, be left to take care of itself. Our difficulty is much more often that we forget too much, so that we want to train our power of remembering. How are we to do this?

The obvious answer to this question is to say that we can improve the memory by practice. By habitually performing tasks of remembering, we might reasonably hope to be able to improve our memories.

For once, however, this answer is shown by careful experiment not to be an adequate one. The trouble is that there is no one thing which we can call "the Memory." Remembering is a name we give to a whole group of different mental activities which happen to have the same practical result of recalling something which has gone before. Sometimes, when we are able to recall a fact about the past merely by reviving some habit formed in the parts of our bodies we use for speech (the larynx, tongue and lips), we say that we have remembered this fact. This, for example, is what is happening when we learn by heart the dates of the kings of England, and it is an important part of what is happening when we are learning a poem by heart.

Quite different from this is remembering by calling up a mental image. When we say that we remember the face of a friend, this simply means that we can call up before our mind's eye a mental image (that is, a mental picture) of his face.

Both of these kinds of remembering are quite different from what happens when we say that we can remember a lecture. In this case, it is unlikely that we can recall

either the actual words used by the lecturer or a mental picture of his appearance. We are merely able to recall the meaning of what he said. This is generally called " logical " memory to distinguish it from the other kinds of remembering which are called " mechanical " memory.

Now, which of all these different operations do we mean to improve when we try to practise our memories? If both were the operation of a single faculty of memory, it would be reasonable to expect that practice in learning by heart would improve our power of recalling the meaning of a lecture. But since in fact they are two quite distinct mental operations, we cannot be certain that practice in the one operation will at all help the other. It may, and, on the other hand, it may not.

We must notice too that the " mechanical " remembering of learning by heart is not, in itself, of much use to us in our adult life. It is very rarely indeed that it is necessary for us to learn anything by heart. What we do want is to be able to acquire the meaning of something—some lecture heard or book read—and for this purpose " mechanical " remembering is of no use.

In fact, it will be found, that practice in learning by heart only helps logical remembering in an indirect and limited way—by increasing our power of willed concentration. If what limits our power of remembering meanings is that we are not able to concentrate sufficiently, then we should practise learning by heart as described in Chapter V, until our power of willed concentration is improved.

The true way to increase our power of remembering is not to try to improve the "memory," but to begin to use more efficient methods of learning. One way of increasing the efficiency of our methods of learning is to learn with more concentrated attention.

The effect of auto-suggestion must also be remembered. It is not so much that one should use auto-suggestion as an aid to remembering itself (although this may sometimes be found useful), but it is necessary to bear in mind that unintended auto-suggestions may often cause forgetting. A confident attitude of mind is the best one to bring to a task of learning. If you say: "I have a bad memory, I shall never be able to remember this," you are unintentionally making an auto-suggestion that you

will fail to remember, and this is quite likely to be effective in making you forget. The reason why many people forget what they try to learn is because they have already made up their minds that they will forget.

Systems for training the memory also generally include training for different kinds of imagery. Some things may be remembered by clear visual images (that is, mental pictures of things seen), others by clear auditory images (or representations to the mind's ear of things once heard). Visual images are not essential (although they are helpful) in enabling us to remember details of things that have been presented to the eyes. It is for this reason that a lecturer does not generally trust to his audience's power of remembering his words alone; he also tries to create visual images by drawing pictures on the black-board, or by illustrating his remarks with lantern slides.

In the same way, auditory images enable us to remember things heard. The person who has auditory imagery is enabled to recall before his mind pieces of music which he has once heard. The absence of auditory imagery must always prevent anyone from going very far in musical appreciation. Such

a person may hear and enjoy pieces of music played in a concert, but when the concert is over they are gone from his mind and from his power of thinking about them until he actually hears them played again. He cannot reproduce them in his mind alone.

It is not certain how far one's power of imagery can be trained. Some experimenters have reported that, by deliberate practice in recalling things by visual imagery or by auditory imagery, they have increased their power of using these images. There is no reason for supposing that this process can go on indefinitely. Apparently some people are deficient and always will be deficient in visual imagery, while others are and always will be deficient in auditory imagery. Those of us, however, who are conscious of a failure in our memory which results from the absence of one kind of imagery, may help to make this failure less by practising that kind of imagery. Even more usefully, we can form the habit of using in our remembering those kinds of imagery which happen to be well developed in ourselves.

There are a few other points connected with the methods of learning which are worth noticing. Although it has been pointed out

by psychologists for a very long time, it is not generally known what is the correct way of learning a long passage by heart. When we were children, we sometimes had to learn a chapter of the Bible by heart, or learn to say the speech of Mark Antony. We were usually taught to split it up into small bits and learn one bit every day and then string them all together at the end.

Experiments have proved that the best way to do a task like this (that is, the easiest and most effective way) is to repeat the whole passage every time and not to cut it up. Splitting a long passage into parts and learning them separately, involves unnecessary work, and what is learned is not so well retained as it would have been had the passage been learned from the beginning as a whole.

It is also not generally known that a task of learning is better performed if the repetitions are distributed in time. If you repeat a passage twelve times in succession, you will not have learnt it as well as if you had made the same number of repetitions with an interval of five minutes or an hour between them. It is as if what has been once repeated must be allowed to settle

down before it is repeated again. After the effects of the first repetition have settled down the next one is more effective.

For the same reason, a task of learning can be disturbed by another task being performed immediately after it. This is like driving traffic over a newly made road before it has become sufficiently strong to bear disturbance. After you have learned something difficult a lapse of say five minutes should be allowed before a new task is attempted. It has been proved by experiment that if you learn one thing and immediately afterwards learn something else, the result will be that the thing you have first learned will be largely forgotten.

It should also be remembered that learning is not carried on efficiently in a state of fatigue, simply because in this condition attention cannot be concentrated. It is a sheer waste of time to try to learn things at the end of a hard day if they can be as conveniently learned at the beginning. More time will be spent when you are tired and the learning will be less effective. This means that the time you can efficiently spend during a single day in pure learning is much shorter than the time you can spend in any

other kind of activity. If hours in school were regulated by scientific principles, the time that children were supposed to spend in learning at school each day would be a great deal shorter than it is now.

Another feature which is common to most mind-training systems, is the practice of various more or less useful tricks for remembering. Some things are remembered more easily than others. A picture, for example, is impressed on the memory more easily than a number. When, therefore, it is necessary to learn numbers, it is useful to convert them into pictures. You may, for example, remember the number 26 by forming a picture of a plate of beef (beef beginning with the second letter of the alphabet and ending with the sixth), 27 may be remembered by the picture of a bog, 28 by a picture of a bath, and so on.

By using a code of pictures like this it is possible to perform feats of memory which would be quite impossible in any other way. There is, for example, a good parlour trick described and performed by Professor G. H. Thomson, in which you allow people to call out to you in rapid succession the name of a large number of different objects, such as

rose, wind, bicycle, park, motor-car, and so on, up to the number of sixty or a hundred. Afterwards you undertake to tell them the position in the series of each particular object called out. You are able, let us say, to tell them that carpet was 67th on the list, and that candle was called out 25th.

The trick you use for this is that when "carpet" is called out to you, you form a mental picture of a frog sitting on a carpet (because frog is the mental picture for 67). In the same way when "candle" is called out you form a mental picture of a bee standing on the top of a candle. You make no particular effort to remember these pictures (it is not necessary), but you will find that when you are asked about the word carpet, the picture of a carpet with a frog sitting on it will come back to your mind, and you will then know that carpet was called out 67th. This is quite an easy trick for anyone to perform who has a reasonable command of visual imagery, and it is one which would be quite impossible by any other method. It illustrates the possibility of using devices of this kind to enable one to remember particular kinds of matter.

In the same way, it is found that sensible

material is learnt more easily than meaningless, and that poetry is learnt more easily than prose. When, therefore, we want to remember more or less meaningless things, such as grammatical rules, it is possible to learn them by making them into a kind of doggerel verse, like that by which schoolboys learn Latin syntax. Provided that somebody else has taken the trouble to make the verse, it is easy to learn in this way a large number of things that otherwise would have to be learned mechanically and so would be retained very uncertainly.

The most important factor of all in remembering is, however, the organisation of our minds by previously acquired knowledge. All that one has learned before on any subject forms a kind of system of pigeonholing in the mind, by means of which new knowledge can be fitted in. This has been called the mind's " apperceptive system."

The mind is often spoken of as if it were a bag or a room which can only contain a certain number of things. It is suggested that we should not try to learn too many things lest the mind should become overcrowded. This is an example of the misleading use of an analogy. The relationship

of the mind to its memories is something like that of a bag to its contents. It differs from it, however, in just this respect, that the more you put into a bag, the less room is there for other things, while the opposite is true of the mind. The greater the store of memories in the mind, the greater is its power of acquiring new ones. The man who has learnt one science finds it easier to learn another, for there is more knowledge in his mind with which his new knowledge can be related. In the same way the man who knows two languages finds it easier to learn a third, while the man who knows three languages finds it easier to learn a fourth, and so on.

This fact, that the more knowledge the mind has the more it can acquire, is one that cannot satisfactorily be expressed by any analogy. It is altogether obscured by comparing the mind with a bag. I tried a little earlier to express something of the truth by comparing the mind with a system of pigeon-holes. Even that, however, does not express the whole truth, for the papers you put on your shelves do not form themselves into pigeon-holes for the reception of yet more papers. Something like this is, however,

true of the mind. It is the memories stored in the mind which make the system of filing and pigeon-holing for new memories; and, as these new memories are added, they too increase the capacity of the pigeon-holing system for yet more knowledge.

It is for this reason that those who have acquired, let us say, a large amount of knowledge about human anatomy or about the religion of Early Greece or about the history of the Pharaohs, will find themselves ready to retain with ease new bits of information about these same subjects. A great part of education is directed towards giving children usefully organised apperceptive systems in a wide variety of subjects about which they will have to learn more later. A boy who has learned electricity and magnetism at school may have learned very little of the actual instruments he will have to use if later he becomes an electrical engineer. He will, however, be able to learn these things, while the boy who knows no electricity will not. The first boy has an electrical apperceptive system while the second has not.

Suppose that anyone wants to learn a new subject, let us say psychology or economics.

He will soon be discouraged by finding that a great part of all the books he reads will be difficult to understand, and those which are so simply written that he cannot fail to understand them, he will find himself unable to remember. The extraordinary rapidity with which we find ourselves forgetting it, is one of the most disconcerting parts of trying to learn a new subject. Yet we should not allow ourselves to be discouraged at this stage. This forgetting does not mean that our brains are not adequate to cope with this subject, but simply that we have not yet formed an apperceptive system in which to receive it. We are putting papers on shelves which are not yet pigeon-holed to receive them.

Moreover, what you are reading is not lost although you cannot recall it. It is itself forming the apperceptive system for new knowledge (here, as we have seen, our analogy with the papers on the shelves breaks down).

It has been said that what is of value to you in learning a subject is not the small amount of it you remember, but the large amount of it you have forgotten. There is a great deal of truth in this, although per-

haps "forgotten" is not quite the right word. The fact that we cannot recall something at will, does not mean necessarily that it is forgotten in the sense of being really lost to the mind. It may have become part of the permanent structure of the mind which makes new acquisitions of knowledge possible.

A last point about remembering which may be noticed is that the importance of precise remembering has been altered very much by the discovery a few thousand years ago of the art of writing. Some people who make a fetish of accurate and detailed remembering seem to have overlooked the practical usefulness of this discovery. In the days before the art of writing was discovered, knowledge was handed down from one generation to another by learning by heart what was told by the elders, and if a fact was not remembered in any mind the knowledge of it was gone for ever. Then accurate mechanical remembering was of great importance. Now, however, a fact you have written down and carefully filed, is as much your permanent possession as one that can be recalled out of your head, and it is better for most purposes to use writing than to

rely on mental remembering for retaining a fact. There are few scientists who do not use filing systems to retain with precision the facts that they want to use in their writings.

WHEN we are lying asleep at night, our muscles are relaxed and we no longer respond by action to any call which may come to us from the outside world through our sense organs. Nor do we respond by action to the stimulations of the sense organs inside our own bodies. Lack of moisture inside the mouth may give rise to thirst. Instead, however, of going to the tap to get some water as we should if we were awake, our muscles remain relaxed.

Instead of external activity, there is a peculiar activity of our minds we call dreaming. We may dream simply that we have got up and gone to the tap to satisfy our thirst, or we may produce a more elaborate and picturesque dream of plunging into cool mountain streams or drinking deep flagons of foaming beer. Our minds have created a vivid drama of satisfying our thirst which seems to us sufficiently real to relieve us of the necessity for that external action which

is actually required but which would cut short our sleep.

Like all purely mental activity, however, dreaming has the disadvantage of producing no real external results. The physical dryness causing the thirst continues in spite of the dream of quenching it. The dryness may, in the end, grow so strong that its demands can no longer be put off by mere dreaming about drinking. It will then stir us to actual action, which means that it will wake us up.

In the same way, when our landlady knocks on the bedroom door in the morning, we may dream that we are sitting in a park listening to a band in which the drummer is sounding a long tattoo, or, perhaps, that we hear a knocking on our bedroom door and that we are getting up and dressing. In either case, the dream is a fairly transparent attempt of our sleeping minds to evade real activity. In the first example, this is done by representing the noise as something which calls for no action on our part; in the second the mind recognises the knocking as a demand for activity but substitutes a dream activity for a real one. In both cases the dream is an attempted evasion of real action; it is trying to preserve sleep.

There are, of course, much more complicated disturbers of sleep than the simple ones which have just been described. The driving forces behind our waking activity are such things as our desire to win money, or fame, or somebody's love, or to provide security for our families. The incomplete satisfaction of such desires in our waking life may produce anxieties which will be serious sleep disturbers if our minds cannot lay them to rest during sleep by efficient dream formation. The restlessness of unsatisfied desire which makes it a serviceable spur to action in waking life, makes it also an enemy of sound sleep. If the acquisitiveness of the business man or the sense of frustration of the lover persist in their own forms during the night, their result will be light sleep, bad dreams, and insufficient rest.

If the mind does its dream-work effectively, however, sleep is undisturbed by unsatisfied desires. The business man achieves success in his dreams, the ambitious man is surrounded by the marks of other people's esteem, and the lover sleeps in the arms of his beloved. Then sleep is deep, and efficient rest repairs the fatigue of the day. It is not until morning that the restlessness and empti-

ness of unfulfilled desire return again to act as spurs to effective action.

The dream way of responding to demands for action is not, however, confined to sleep. Even during our waking hours, the formation of day-dreams or phantasies is part of our mental life. While these are not identical with the dreams of sleep, they are produced in the same general way. They are dramas of fulfilled desire. In our day-dreams, our ambitions are fulfilled, we win the esteem of other people and the affections of those we love, we carry out actions in which our physical or mental limitations are overcome, and we transport ourselves from the depressing industrial towns in which we are forced to earn our living and recreate ourselves on the mountains or sunlit seashore which our hearts desire. This is all, however, without immediate real effects on the outside world.

We may say, in fact, that there are two ways in which we can respond to any situation or feeling which impels us towards action. We may really act or we may dream. The clerk who realises that his salary is too small to enable him to marry may study a foreign language in order to

fit himself for a better-paid post, or he may be content just to picture himself in a position of responsibility. The student who realises that he does not know enough of his subject to pass his examinations may study his subject more diligently, or he may construct a phantasy of himself passing with first-class honours and receiving his degree before an admiring audience. On the side of actual activity, there is the advantage that it alone can produce real results; on the side of dreaming, there is that aversion to the hardships of real activity which is to be found in even the most energetic characters.

Nothing can be more fatal to the achievement of any ambition than this substitution of dreaming for real activity. It is a constant danger of all systems of mental culture that they are liable to encourage the dreaming rather than the acting habit of mind. There is a system which asks its students how long in each day they spend in thinking of their ambition, and implies that they ought to spend at least an hour a day in such thought. I think this is a dangerous question. A better question would be " How long in each day do you spend in actual activity towards realising your ambition? "

The clerk whose thoughts were occupied with his dream of becoming a managing director while he was engaged in adding up figures might easily find that his dismissal for incompetence took him further from the fulfilment of his ambition than he was before.

Such systems remind us that no change in the condition of a single individual or of society as a whole has ever been brought about unless it has first been imagined by somebody. That is true, and it alone would be sufficient reason for refusing to regard dreams as unimportant. There is, however, another truth which is liable to be overlooked. So long as a change remains merely imagined by someone and is not translated into action it is without real effects. It remains a mere dream.

You will do very little for the mitigation of poverty by giving a shilling to a man in distress, but even that little will be far more than will result from your merely dreaming that you have reorganised society from top to bottom. Such dreams are valuable and necessary, but only if they are translated into some effective action, however little it may accomplish.

In the early days of the great war some

people met together to " will " peace. They proposed to take no action, but were supported by a vague belief that mental conditions translated themselves into physical realities without any efforts being made to that end. It was a mere dream and not a " will " that they were producing, and any action, however trivial, would have had more real outside effects.

Just as dreaming of action is not acting, so dreaming of knowledge is not knowing. Since study is a hard kind of action many people are willing to substitute dreaming of knowledge for real learning. Hence the attraction of a certain kind of popular manual on scientific subjects in which difficulties are evaded, uncertainties and exceptions to accepted rules are forgotten, and the reader is led to believe that no more arduous discipline of thought is necessary to fit us to make an intelligent judgment on a scientific theory than that needed for solving magazine puzzles. The reading of such manuals bears to real learning about the same relationship as being pulled along a valley by a train bears to the arduously won joy of adventure on the mountain tops. The heights of science are open to some

extent to everyone who has time to devote to study and who is not feeble-minded, but they are open to no one (not even to the most gifted) without mental discipline and hard work.

The science of psychology suffers in particular from such substitutes for real learning. So we find many people who feel able to give a just and final judgment on such questions as psycho-analysis, the existence and nature of human instincts, and modern theories of education with no more knowledge of these questions than they have acquired from their daily papers.

Simple manuals serving as introductions to difficult branches of knowledge are not, of course, in themselves harmful. These are often written by men eminent in research in their own subjects. Sir William Bragg's lectures on electrons and atoms can interest the person entirely ignorant of physics, but they would never lead him to suppose that a full understanding of this subject could be attained by such an easy path. They would be more likely to supply him with the interest which would stimulate him to the effort necessary for more advanced study of the subject. A person possessing the

true spirit of the mountaineer but ignorant of the ways of mountains might begin by being led by a guide up easy slopes. He would never, however, make his acquaintance with the mountains by being drawn in a donkey cart through the valleys.

The temptation to substitute dreaming of knowledge for the real activity necessary to gain it is one that remains at all stages of learning. It is always easier to spin ingenious theories out of one's own mind than to win them by the impartial study of hard facts. Many men who have started as earnest students of reality have lost their way in the dreamland of fanciful theorising. Perhaps all do to some extent, and those who have made the great contributions to human knowledge have simply been those who resisted this temptation most successfully.

Whole nations have forgotten to study reality and have developed an intellectual culture which has had for its science mere speculations unchecked by fact—dream knowledge instead of real science. The seven million tiny vessels traversing the body called *nadis*, the latent and sacred energy of *Kundalini*, and the *Astral body* are some of the " discoveries " of this dream science.

Probably the chief reason for the survival amongst ourselves of fragments of such fanciful learning is that belief in them serves both mental idleness and the desire to feel that we know more than other people. It is easier to acquire the jargon of the astral body than it is to learn the names and functions of the spinal nerves from an anatomical textbook. Also this jargon can be made to sound very impressive to ignorant people. The textbook will give us real knowledge, however—knowledge which can be checked by observation and experiment —while the other is nothing but dream knowledge.

It is not, however, only from the pre-scientific systems of the East that we can draw this shadowy imitation of real knowledge. Whenever in our search for knowledge we lean back in our arm-chairs and spin fancies from our minds instead of applying ourselves to the study of reality, we are weaving a similar dream of our own. Many books are published every year which are produced by no more arduous mental effort than this. They are very vague and very general and very dull, and because most of their readers cannot understand

what they mean, their authors think that they are "philosophical." There could be no more cruel abuse of a noble word than to call such mystification "philosophy." A true philosophy is one that is in close touch with reality.

The danger of dreaming, then, is that it produces no real results. This is not to say, however, that dreaming serves no good end. So long as dreams are kept in their right place and are not allowed to interfere with action, the ability to dream is of no less value than the ability to act.

It is true in a sense of every aim that we accomplish that it was a dream before it was an accomplished reality. Our ability to plan far into the future, and to carry out an arduous course of training in order to fit ourselves in the end for a desired position, depends on our ability first to dream and then to use our own efforts to convert those dreams into a reality. Slavery could not have been abolished in America if Lincoln and others had not first dreamed of a condition of society in which all men had legal freedom. Nor would it have been abolished if these men had not had the energy to make this dream into a reality.

So dreams are not always idle substitutes for action. They may be spurs to action. It is usual to give a special name to those dreams which lead to action and to call them *ideals*. A medical student who dreams of himself as a famous and successful surgeon may find that this dream provides the necessary incentive to make him apply himself hard to his work, which is often laborious and dull. This is an ideal, for it obviously serves a useful purpose in his life. If, however, his dream took the form of picturing himself as an operatic singer applauded for his wonderful tenor voice, this would clearly be a useless dream, however pleasant it might be to the student himself.

But even an ideal may degenerate into an idle dream if it is indulged in for its own sake. If the medical student sits in his armchair picturing himself as a successful surgeon when he ought to be studying a textbook on anatomy, he is indulging in an amusement as useless to action as if he were engaged in the operatic tenor dream.

Whenever we are engaged in a task which we are not compelled to do by somebody else, we shall find that we can help ourselves to do it by encouraging ourselves with the

picture of what we hope to have accomplished at the end of it. Writing a book is, for example, such a task. But, since work is irksome while dreaming is easy and pleasant, we shall find it necessary many times a day to kick ourselves into actual activity instead of merely dreaming about the finished result.

Dreams, of course, may sometimes be worth while in themselves apart from any value as stimulants to action. A work of art is just a dream which has been given an external form so that its beauty can be communicated to other persons. Its value may simply lie in its beauty. All dreaming, even when it remains in the mind of the dreamer and is incommunicable to other people, has the same kind of value. Nothing that makes men happier can be without value. The mental pictures of green hills and sunshine which may lighten the drab day of the worker in a smoky industrial city have something of the same kind of value as Keats's *Ode to the Nightingale.* Even if our dreams served no useful purpose in action, we should be very much poorer without them.

Perhaps it is hardly necessary to say this,

for few of us are inclined to undervalue dreams. Most of us are more inclined to forget how little dreams can do unless they are translated into actions. We like to judge ourselves favourably because of our fine intentions, when it is really our active efforts to accomplish those intentions that matter. To lose touch with reality and live entirely in a world of our own beautiful dreams is a form of insanity which ends in a mental decay in which probably even those dreams are lost. Effort on the plane of reality is a price we must pay for the privilege of sane and healthy dreaming. If our dreams even begin to take the place which should be occupied by reality we begin to become ineffective. We are mentally only half alive.

ANYONE who reads the advertisements of systems of mental culture will notice what a very large number of them promise to cure their students of shyness, to give them self-confidence and a "magnetic" personality which will make it possible for them to dominate other persons. These advertisements may be illustrated with some such picture as that of a previously diffident clerk demanding, with his chin thrust out and his chest inflated, a rise in salary from his employer.

There is no doubt that the sense of inferiority is a very great evil for those who suffer from it. The shyness which results from it and the loss of self-confidence or even of self-respect destroy both efficiency and happiness. To be able to give some help to people who suffer in this way should be one of the aims of applied psychology.

We must feel much less sympathetic with the ambition merely to dominate other

people. If psychology could turn us all into chin-thrusting, chest-thumping personalities, we should not be any better off, for there would be no one left to be dominated. The human race as a whole would certainly suffer, for such mental monstrosities could not be expected to get on with one another and would most likely exterminate each other in a few years.

Although excessive timidity and lack of self-confidence are obvious sources of inefficiency in all that part of the business of life which is concerned with our relations to other people, efficiency is not to be gained merely by learning to dominate others. We do not best move through a crowd of people by going forward in a straight line and pushing everyone else by brute force out of our way. A better method is one which combines pushing forward and giving way. We walk round some of the people who are in our way, and occasionally step back for someone moving in the opposite direction; we try to take advantage wherever we can of currents of people moving in the same direction as ourselves, adjusting our movements all the time both to the requirements of other people and to our own aim of getting to the

other side. In this way, we get to our destination not only without causing annoyance to anyone else, but also more quickly and with much less trouble to ourselves than if we had taken no notice of other people but had just pushed them out of the way.

This is equally true of all that part of our life in which we are concerned with other people. However definitely we may have decided on our aims, the best way to attain them is not just by pushing straight forward and ignoring the requirements of other people. We have instincts both of *submission* and of *assertion*, and it is only by a balanced exercise of both that we can keep a harmonious and efficient relationship with the people with whom we have to deal. If we are the victims of a sense of inferiority which makes us too submissive, we shall never attain our goals, because we shall be pushed on one side by the more forceful personalities of those with whom we are competing. If, however, we are too assertive, we are likely also to miss our aim, for we shall arouse the active antagonism of other people, and cut ourselves off from the advantages of co-operation. There are not many things worth gaining

which we can gain alone, without the active co-operation of our fellow men.

If we went to consult a doctor about a serious illness, it would be of no help to us that we had taken a correspondence course in the development of a dominating personality which enabled us to impose our will and our opinion on him. This would merely put us into a position in which we could not profit from the knowledge and experience of the doctor. If we died as a result, our survivors could more justly write on our tombstone *Here lies a pig-headed individual* than *Here lies a magnetic personality.*

It is equally true, of course, that the doctor would fall short of full usefulness to his patients if he lacked that element of character which enabled him to impose his opinion and his will on them. We all require a certain ability to dominate in some situations and a certain ability to submit in others.

Even when we admit this, however, it remains true that lack of self-confidence and excessive shyness are always unpleasant and may be a serious disability. No one who suffers from them can be satisfied with the efficiency of his mind. They are common (and perhaps unavoidable) in the period

between childhood and adult life, but the normal person outgrows them as he leaves adolescence behind him. If he is so unfortunate as to find that he does not, what can he do about it?

First of all, we must notice that there is one kind of shyness which stands in a class by itself because it is found in nearly everybody to begin with. This is the lack of self-confidence which assails us when we first try to speak in front of an audience. This is probably a real instinct and is the timidity which prevents the ordinary member of a herd of wild animals from assuming the position of leader. In the wild condition it was a useful reaction because the most efficient hunting or fighting organisation is that herd in which the dominance of the herd leader is most unquestioned.

However useful this peculiarity of character may have been to our remote ancestors, it is a great nuisance to the man or woman who must begin to speak in public either for the advancement of some cause or in order to earn a living. If you are in this position you can comfort yourself with the reflection that you are facing a difficulty which practically every public speaker has faced and

overcome. It is a disability which mere habit will get rid of. There are examples of people who find that after years of public speaking, they are as nervous before an audience as they were when they began, but these are rare. Most people find that the habit of speaking before an audience makes it as easy to speak in that way as to carry on a conversation with their own friends.

This fact should prevent the nervous beginner in public speaking from being too much depressed by his nervousness, but it does not solve his immediate problem of how to get on until his nervousness disappears. The principles to be applied are the same as those described in an earlier chapter on the control of other emotions.

There is first the principle of the control of emotional expression. Even though you cannot by willed effort stop yourself from feeling timid in front of an audience, you can stop yourself from showing the outward signs of timidity. You can stop your knees from knocking together and your voice from quavering. If you can succeed in showing no outward sign of your feeling of nervousness at the beginning, half the battle is won,

for your nervousness will rapidly grow less as you go on speaking.

If willed effort is not sufficient to keep down the outward signs of nervousness, auto-suggestion should be used. A short formula should be repeated saying that you will speak confidently and well, and (since too much anxiety about your speech is a great cause of your nervousness) that the whole business does not matter much. This last part of your formula can be quite properly used if (and only if) you have previously done everything you can by strenuous preparation to make your speech as good as it can be. Much of your nervousness would disappear if you could fully realise that the great course of the universe would be unaltered by the good or bad impression your speech made on the persons who heard it.

It will be found a good plan to repeat this formula several times during the few days just before the dreaded event, particularly when the thought of the intended speech is already making you feel nervous. It will be found helpful to form a mental picture of the audience as they will appear from the platform and to look them straight in the face while repeating the formula. It should also

be repeated (silently, of course) immediately before speaking. You should look boldly round the audience before speaking, and at them while speaking. By the use of these methods it should be found that the fear of an audience can be effectively controlled.

A more difficult problem, however, faces the man who finds himself timid and lacking in self-confidence in all his contacts with other persons, and who finds that mere habit does nothing to remove his misfortune. He it is who is attracted by the advertisements which promise him a " magnetic personality " and the power of dominating other people. He suffers from what the psycho-analysts call an " inferiority complex."

The methods which have just been mentioned for the normal person overcoming his fear of speaking in public apply, of course, also to the man suffering from a real inferiority complex. He too must remember that he has a certain amount of control over the expression of his emotion of fear even though he has none over the emotion itself. A confident bearing with head held up and voice firm will both help to remove the inner lack of self-confidence and also hide it from other persons. The shy person will find

help too in formulæ of auto-suggestion suggesting self-confidence, clear and unhesitating speech, and freedom from the inner doubts which assail him when he tries to influence other persons.

His danger here is what is technically known as *over-compensation.* If the practice of a self-confident voice and manner and the use of auto-suggestion merely change him from a shy and diffident man into an arrogant and self-assertive one, not much will have been gained. Arrogance does not help us in our relationships with other men any better than does timidity, and it is a much more unpleasant quality of character. This replacement of timidity by arrogance is just what is likely to happen as a result of the methods just described if no attempt is made to attack the deeper roots of the trouble.

Lack of self-confidence and timidity are merely surface results of a deep underlying doubt and under-valuation of ourselves. Auto-suggestion and the practice of a self-confident manner leave this doubt untouched, so instead of expressing our doubt of ourselves in timidity we try to hide it by an outward show of arrogance. The arrogance, however, is very unlike the calm self-reliance

of the man who has no doubts of himself. The voice tends to be too loud, and we are self-assertive when self-assertion is not necessary.

We do not need a training in psychology to recognise the difference between the man who is really self-confident and the man who puts on the manner of self-confidence in order to hide his deep-seated sense of inferiority. In just the same way, no sensible person supposes that the man who shows habitual foolhardiness in exposing himself to unnecessary danger is really (as he would like us to believe) a man in whom the sense of danger is absent. It is more likely that he indulges in these freaks as an over-compensation for a deep-seated fearfulness. We are not surprised if the same man shows utter cowardice in the presence of an unexpected and unavoidable danger.

It is for this reason that we have spoken of an *inferiority complex* and not merely of the feeling of inferiority. It is something more complicated than a mere feeling that the uncontrollably shy man is suffering from. Whether its outward expression is a timid manner, or a boastful manner, or a pompous manner, or an affected and "cultured"

manner, the root trouble is the same. It is an inferiority complex expressing itself in various objectionable ways. The aim of the man suffering from the sense of inferiority should be to cure the disease which lies at the root of his trouble and not merely to change its symptom into one which may be even more objectionable than mere shyness.

Before we discuss how this can be done, we must notice the dangers and disadvantages of one of the specifics recommended for the domination of other persons. This is the copying of the methods used in hypnotism.

It is found that many people can be put into the hypnotic state and in that state can be made to do or believe whatever the hypnotiser wishes, by the use of methods which can obviously be imitated in everyday life. The hypnotiser looks straight into his patient's eyes and repeats his requirements over and over again in a calm, commanding, and monotonous voice. He does not argue or reason with his patient but simply commands. It was supposed at one time that the hypnotiser had to make a great effort of will in order to dominate his patient, until Galton discovered that no special effort of will was required, but that all the hypnotiser

need do was to adopt a manner of speaking and acting which would suggest to his patient that he was exerting the irresistible force of an inflexible will. So he was able to dominate his patient with a completeness which might rouse the envy of the most successful street-corner seller of a worthless drug for curing all diseases.

Similar methods are, in fact, used by the street-corner seller. They are often used also by orators and by the more bullying kind of reputable salesmen. These people try to influence other people's actions for their own ends by loud-voiced and confident repetition without reason or argument, and, if they are dealing with a single person, by looking him straight in the eyes. Is this the method which psychology recommends to us as the best for attaining efficiency in our relationships with other persons?

The most important part of the answer to this question is that even if these methods were as successful as their advocates say they are, they would be morally wrong. It is no more justifiable to use mental violence against other persons than to use physical violence. The injury to a man which may result from this sort of violence may be no less than if we

had persuaded him to buy our goods or to subscribe to our creed by bashing him in the face until he did. The injury will show less because it is in his mind and not in his body.

I suggest that the circumstances in which these hypnotic tricks are justifiable are very rare indeed. Perhaps they are entirely confined to the doctor's consulting-room. There are very rare circumstances in which we are justified in using physical violence against another person. If we are rescuing a man from drowning and he clutches us in such a way that he is endangering the lives both of himself and his rescuer, we are justified in rendering him unconscious by a blow on the jaw. Circumstances of a similar kind are necessary to justify the use of hypnotic tricks for forcing your will on another person. The individual who uses them for selling a patent medicine or a metal polish should be locked up.

A further point to notice is that such methods are not always as successful as their advocates would have us believe. When dealing with a crowd, one can certainly produce greater immediate effects by confident repetition than by argument, but there is good reason for believing that effects pro-

duced in this way are not very lasting. Every member of a crowd is also an individual who will think over in solitude what he has heard. If it has been nothing but windy and empty repetition, it is not likely to appear very convincing to him as he reflects over it by his fireside, even if he was carried away at the time of hearing it.

The effects of using hypnotic tricks on an individual may be even less what the person using them expected. The subordinate who uses the hypnotic gaze and manner when asking his employer for a rise in salary may find that his employer has been studying the same book on applied psychology as himself. In that case, the applicant is likely to find himself kicked through the door instead of being promoted.

Even those people who know no psychology are generally provided by nature with a fairly efficient mechanism for protecting them against too unscrupulous attempts to overthrow the independence of their wills. Such attempts are likely to arouse the attitude of " contra-suggestion " or refusal to act in the way expected. A judge who is too positive in his directions to the jury may find that they bring in a verdict against his

directions and against the evidence, simply because they were moved to an attitude of antagonism by his too obvious attempt to dictate to them. Similarly, a man may refuse to buy an article for no better reason than that, without knowing the technical name for the process, he has recognised that the seller is trying to influence his judgment by the kind of psychological trickery we have been describing.

I am frequently visited by people who want to sell me apparatus for the laboratory. Some of these have learnt their salesmanship in the hypnotic school, and they stare me down and talk in loud confident voices. They are at a loss, however, when I ask them about some technical detail of the apparatus. They believe that self-assertion is more important for a salesman than accurate knowledge. These are not the ones to whom I am most inclined to give orders, and I do not think that I am very different in this way from other people. If, in the business world, you can best sell things by loud-voiced self-assertion, then business men must be bigger fools than they are generally supposed to be.

Chapter XI The Destruction of the Inferiority Complex

WE must return, however, to the problem of the methods of dealing with the root causes of the sense of inferiority. The person who suffers acutely from this may take some comfort from the fact that it is an affliction which to some extent nearly everyone has suffered from. The man who has always been naturally and completely without doubts of himself must be very rare. A haunting sense of inferiority is common at adolescence and immediately afterwards, but most people manage to deal with it satisfactorily at this time, while a few others carry the same affliction through the rest of their lives.

The beginning of it may lie in childhood. The foolish mother who says in her daughter's hearing " I wish Amelia had been a boy," or the foolish visitor who says " Now that your little baby brother is born, Mother won't love you any more," may sow in the child's mind a seed which will ripen into an

inferiority complex from which he or she will never in later life be free. There are many crimes which are not punishable by law, but few more cruel than this one.

There may, on the other hand, be a more real cause for the development of a sense of inferiority in childhood. The child, for example, may be less beautiful or less intelligent than his brothers and sisters. The evil will, of course, be greater if the parents show preference for the others, but it may be there in any case. Or, there may be an actual bodily inferiority, a deformity or serious bodily weakness. Hunchbacks are proverbially liable to display the unpleasant traits of character which develop from an inferiority complex. Or the child may find himself looked down upon because he is of a race regarded as inferior by the majority of people amongst whom he lives, or because he is of mixed blood and is despised by the men and women of both races from which he has sprung.

There is no biological reason for the moral degeneracy often found amongst half-caste people. A man half Chinese and half English is not physically or mentally worse off than if he were of pure race. He may,

however, be mean and degraded simply because from childhood he has found himself despised alike by the Chinese and the English. In places where the half-caste is not despised he is not found to be mentally or morally inferior. There are, no doubt, real differences between people of different races, but we may well ask how much of the supposed inferiority of the races we believe to be inferior to ourselves may be due to a racial inferiority complex, produced by our triumphant attitude of superiority.

An inferiority complex may, then, have started in a humiliation of childhood the reality of which has long since passed away, or it may have its roots in a lifelong humiliation through bodily defect or membership of a despised race or caste. In either case we must deal with it as it exists at present. It is not wise to try by ourselves to dig out its roots in the distant past. This is what is done in the method of treatment known as psycho-analysis. This treatment under the direction of an expert analyst may sometimes be the right one for severe cases. It is, however, a long process and it is not one we can undertake by ourselves.

For those who are trying without outside

help to cure themselves, the advice undoubtedly is to leave the past alone and to fight the evil as it exists at present. It is the present under-valuation of yourself that is at fault, and the only method is to drag this under-valuation into the clear limelight of consciousness and to destroy it by understanding it, by laughing at it, and by refusing to accept it any more.

It is not being a hunchback or having a coloured skin that makes you feel inferior. It is not even the fact that other people think less of you for these things. It is your accepting the valuation of other people and despising yourself that is the real trouble. This is what you must not allow.

Those who have any tendency to undervalue themselves but who have no ground for it in a supposed bodily or racial inferiority find rich material for the creation of an inferiority complex in customary social valuations. The desire to associate with the rich and idle; embarrassment in their presence because our manner of dressing, eating, and speaking are not the same as theirs; or even loud assertion of our equality with them, are all marks of the acceptance of a superstition

which must be cast out if we wish to be free from the sense of inferiority.

In their hearts, most people must recognise that the fictions of social position are superstitions more worthy of savages than of thinking people. Yet the whole system is often so worked into the stuff of their minds that many persons prefer any folly, unhappiness or embarrassment to a courageous repudiation of it.

Why, for example, should a man be tortured with embarrassment because he is conscious of being dressed differently and of handling his knife and fork differently from the prosperous-looking man at the next table? He does not reflect that the prosperous-looking man might as sensibly be embarrassed because his own dress and manners are not the same as his neighbour's. These conventions differ in different places and there is no absolute standard of right and wrong. The prosperous man maintains (very sensibly) the fiction that his conventions are absolutely right, while his shy neighbour has foolishly accepted the same fiction.

The remedy for an inferiority complex must often be to remove from the mind the

fictitious valuations of caste. The shop-assistant who looks down on the general servant is accepting a system of judgments by which she is logically led to accept the typist's similar under-valuation of herself. We cannot accept a system which leads us to despise others without being in danger of being led by it to despise ourselves, and it is this despising of ourselves (unrecognised by consciousness) which is an inferiority complex. If we are to keep our respect for ourselves, we cannot afford to allow ourselves the luxury of thinking ourselves superior to others who follow different occupations, who have differently coloured skins, or even who have less intelligence.

If we realise that this deep-rooted under-valuation of ourselves is at the root of our inferiority complexes, the general rules for dealing with these will be clear. We must undertake a thorough revision of our attitude towards ourselves and towards other people. Controlled thinking will help us to this end. Science, religion and common-sense will all provide reflections which will help us to win a sane outlook on ourselves and on other people.

No one who has fully realised the position

of the human race clinging precariously for a little time to a globe hurtling through space, with no protection against collision with one of the multitude of other globes, will feel unduly lifted up by the fact that he has a superior social position or depressed because he hasn't. The varying gifts which separate individuals will seem small too to one who fully realises the long process of evolution which has gone to the making of man. What a long and laborious process was the making of the backbone in the vertebrate animals. The hunchback may reflect that to have a backbone at all is a finer thing than merely to have one that is straight, and a man may certainly be prouder of having a skin than merely of having one without colouring matter in it.

So we can all cultivate a pride in the things we have in common with all men, and only allow ourselves a very small allowance of satisfaction in the gifts which are peculiar to ourselves. We cannot hope to get rid of this satisfaction altogether and, in any case, it is of use to temper the inferiority we may be led to feel in the superior gifts of others. All of us are peculiarly gifted in some respects, and it is foolish always to put ourselves into

positions in which our inferiorities are too obvious to ourselves. If we are not good-looking, we may be good speakers, and if we are not good speakers we may have a fine sense of humour. If we are no good at football, we may have a rare gift for tiddly-winks; so we shall be wise not always to be trying to play football but sometimes to allow ourselves to display our gifts at tiddly-winks. We ought to play football as well for the sake of our humility. It is neither pride nor humility that we are aiming at, but at a serviceable balance between the two.

While practising such a discipline of thought and behaviour in order to get rid of the inferiority complex in all of its forms and to attain real freedom in our relationships with other men, we can, of course, use auto-suggestion in order to relieve the distressing symptoms of shyness, etc., when they occur. The student who is suffering from stage fright at the prospect of a viva-voce examination to-morrow cannot wait until his views of his relation to his fellow men have improved before he escapes from his paralysing shyness. He must have relief now, and his method will be to use auto-suggestion as described in the last chapter. Only he

should remember that he is merely giving relief to a symptom and not curing the disease.

Another thing that may be wrong with a person suffering from an inferiority complex is that he is unnaturally engrossed in what other people are thinking about him. We are all sensitive to other people's opinion to some extent, and it is right that we should be. But if we are always suffering at the thought of their real or imaginary disapproval of our behaviour or of our dress, then we must recognise this habit and destroy it as we destroy other bad habits.

When we have properly subdued our inferiority complexes, we shall not, of course, show our independence of other people's opinions by discarding our collars and spitting on the pavements. Such a vigorous rebellion against harmless conventions does not show that one is really free from them, but suggests that one has an inner slavery to them against which one is kicking. The man really free from slavery to the opinions of others will conform to conventions which do no harm and reserve his opposition for the many customary ways of behaving and feeling which are cruel, inefficient and harmful.

MOST of the systems of mental self-development which we have been discussing have been parts of the practice of religious systems. That is clearly not just an accident. Part of the driving force behind man's ceaseless quest for religion has been his need for the development of an attitude and a system of beliefs in which his restlessness and his fears, his worries and his inefficiencies may disappear.

The deepest and most essential part of the faith of all religions is the conviction that our business is to identify ourselves with a purpose infinitely more important than any of our private ends. This purpose is what the religious man calls "the Will of God." In this phrase, the word God has been used in the most widely different senses. By most religious men God has been believed in as a personal Being; others, however, have thought of Him only as an impersonal force. His Will also has been differently understood,

and the conception of it has varied from the ruthless massacre of unbelievers to the establishment of justice, kindness, and equality of opportunity for all men.

However it may be believed in, it is evident that a real acceptance of the Will of God lifts the religious man from the region of worries and fears. One who truly feels himself as part of an infinite purpose cannot worry about his own failures, for he believes that his own efforts are only part of a process which can go on without them, and that although his efforts may be directed towards God's ends, God can work towards these ends by other means as well.

I have suggested in earlier chapters reflections which can be used to reduce the strength of particular emotions. The religious man will draw many others from his religious faith. The conception of all men as children of God should be enough to destroy unreasonable anger against other persons, or pride of race and all the other emotions connected with complexes of superiority and inferiority. In the same way, religious considerations should be found strong enough to remove all attitudes of worry and anxiety.

We must not, however, make the mistake

of supposing that the objects of the teachers of religion are the same as those of the mental culturist. In a sense they are opposites. The religious teacher tries to persuade men to believe in God and to take a religious attitude towards their conflicts and losses. He then shows that, having this faith, they must release themselves from the worries and fears which are inconsistent with it. He does not tell them to believe in God because they may so escape from their worries and fears, but that they must abandon their worries and fears because they believe in God.

Jesus taught his disciples not to worry because they saw how God took care even of the birds and the flowers. A mental culturist might invert this teaching and tell people to apply psychological methods to induce a belief that there was a God who took care of the birds and flowers, because in this way they could get rid of worry. This, however, would be to try to buy the consolations of religious faith at the price of mental dishonesty.

Whatever particular beliefs a religious man holds, it will be through these that he strives for mental efficiency. Also we may notice that if the religious attitude of mind

is accepted, mental efficiency is no longer a low or utilitarian ideal. If we were only busy with our own ends it would matter to no one but ourselves whether we pursued them efficiently or not. But if there is an Eternal purpose which we can help or hinder by our actions, then it becomes of infinite importance how effective our action is. Mental efficiency becomes a religious duty.

It is a common error to associate especially with religion, those kinds of activity which are ineffective. The useless action of giving a penny to a beggar is supposed to be an act of religious charity, while religion is supposed to have nothing particular to do with an economic study of the causes of poverty and with political action to remove those causes. Yet these may be effective actions, while the first certainly is not.

In the same way, bathing the wounds of an injured person (which may be a dangerous operation for him if the water is not properly sterilised) is thought of as a religious act, while the scientific research and the medical organisation which make effective healing possible are not.

It is true that giving a penny to a beggar may be a religious act because it is done for

the love of God. But there is something wrong with our religion if the love of God cannot also drive us to the effective action of economic research and political action.

So we ought not to regard as specially religious those types of mental activity and those organisations of mind which are inefficient. The religious man should not tolerate in himself the vague benevolence and general ineffectiveness which lead to no serviceable action. Mental inefficiency is an offence against the God whose instruments we are.

PART I

SUGGESTION

CHAPTER I.

WHAT IS SUGGESTION?

While the majority of thinking people know what is meant by the word "suggestion," in its modern psychological sense, yet very few of them are able to give even a fairly good definition of the term. And this difficulty is not confined to the general public, for even the writers on the subject of Suggestion seem to experience the same trouble in defining the term, and many of them have seemingly given up the task in despair; for they have plunged right into the middle of the subject, leaving the reader to learn what Suggestion *is* by what it *does*. But, notwithstanding this difficulty, we think it well to begin our consideration of the subject by at least an attempt to define the term, and to give a preliminary explanation of its scientific meaning.

The word "suggestion" is derived from the Latin word "*suggestus,*" which has for its base the word "*suggero,*" meaning: "To carry under." Its original use was in the

sense of a "placing under" or deft insinuation of a thought, idea, or impression, under the observant and watchful care of the attention, and into the "inner consciousness" of the individual. The word, as generally used, indicates the use of a hint or other indirect form of calling a matter to the attention of another. But beyond this use, there has arisen a secondary, and more subtle employment of the word, i. e. in the sense of a sly, guarded *insinuation* of an idea, in such a way that the hearer would fail to understand that he was receiving a hint, but would be apt to think that the idea arose in his own mind, from the workings of his own mentality. The word "insinuation" gives one the nearest idea of this form of suggestion. The word "insinuate" means: "To introduce anything gently, or by slow degrees; to instil artfully; to hint guardedly or indirectly; to intimate;" —the main idea of the term being "to creep in." And, indeed many suggestions (in the scientific sense of the term) are so *insinuated* into the mind.

But among psychologists, the word began to take on a new meaning, i. e. that of the in-

troduction of anything into the mind of the other, in an indirect and non-argumentive manner. One of the dictionaries defines this sense of the term as follows: "To introduce indirectly into the mind or thoughts." And, later, psychologists began to use the term in a still broader sense, i. e. that of the *impression* upon the mind by the agency of other objects, such as gesture, signs, words, speech, physical sensations, environment, etc. And this use was extended later, to meet the requirements of the adherents of telepathy, who employed it in the sense of the "insinuation of ideas by telepathic means," the term "mental suggestion" generally being used to distinguish this particular form of suggestion.

The comparatively recent interest in, and discoveries regarding the great subconscious area of mind, caused a new interest to attach to the use of suggestion, for the majority of the writers held that this subconscious region of the mind was particularly amenable to suggestion, and that to this part of the mind all suggestions were really directed and aimed. The "insinuation" was held to be the artful introduction of the thought into this region

of mentality. Many theories were advanced to account for the phenomena of the subconscious in its phase of the suggestible-mind, and the discussion still rages. But, no matter what theory may triumph in the end, the fact of the existence of the subconscious region of mind has been firmly established. While the theorists are disputing about names and generalities, a great army of investigators are uncovering new principles of application, and new facts of phenomena regarding this wonderful part of the mind. While the theorists are disputing about the "Why," the investigators are finding out much about the "How." The subject has now reached the stage where it may be divested from mysticism or "supernaturalness," and studied from a purely scientific position. Subconsciousness without Suggestion, would be like "Hamlet" without the Prince. The two subjects are bound closely together, and it is difficult to consider one except in connection with the other.

In order to understand the modern psychological use of the word "suggestion"—which is the use that we shall make of the term in this book,—you must make the broad distinc-

tion between the ideas accepted by the mind following the employment of logic, reasoning, demonstration, proof, etc., on the one hand; and *impressions* made upon, or ideas *induced* in the mind by other methods. The words "Impression" and "Induce" will give you the best idea of the effect of suggestion. When an idea is placed in the mind of a person by Suggestion, it is always placed there by one of the following three general methods:

I. Suggestion by means of *impressing* the fact upon the mind by firm authoritative statements, repetition, etc., in which the suggestion acts as a die upon the molten wax; or

II. Suggestion by means of *inducing* the idea in the mind, by indirect insinuation, hint, casual mention, etc., by which the mind is caught off its guard, and the instinctive resistance of the will is escaped; or

III. Suggestion, generally along the lines of association, in which outward appearances, objects, environment, etc., act to *both impress and induce* the idea into the mind.

Of course there are cases in which several of these three methods are associated or combined, but a careful analysis will show that

one or more of the three are always in evidence in any and all cases of Suggestion.

To some, the above statements may seem strange, for to many the arguments of a person are held to be the strongest forms of suggestion, impression and induction. But a little analysis will show that there is far more to Suggestion than argument. In the first place mere argument for argument's sake is not a strong suggestion. Men may argue for hours, without any special object in view, and after a great flood of words, all the parties thereto will go on their way, unconvinced, unimpressed, and with no new convictions or ideas "induced" in them, unless under the latter classification may be included the frequent "impression" or conviction that the other party to the argument is either densely ignorant, a fool, bigoted, or else an unmitigated bore. The twelfth juror, who complained of the "eleven stubborn" fellow-jurymen, was not especially amenable to the suggestion by argument; although the same man undoubtedly could have been swayed by the employment of a more subtle form of influence. It is true that often argument

is necessary to brush away certain objections to certain ideas, but after that is done the real work of Suggestion is performed by the person wishing to make an impression. As a rule Suggestion is not operated by opposing will to will; argument to argument; or logic to logic. On the contrary, it generally operates by insinuating itself under, over, or around the argument, will, or logic; or else by an authoritative statement, repeated as often as possible, without proof, and avoiding argument. And even where proof or argument is employed, it will be found that the Suggestion is in the form of the main statement, and that the argument and proof are merely the "stage-business" of the performance.

In the form of Suggestion, in which Impression is the method employed, the action is generally direct and open. The "strong men" frequently employ this method effectively, carrying it through by sheer force of personality and real or fancied authority. Where Induction is the form employed, the method resembles that of the diplomat, and tact, *finesse,* and subtle insinuation are the forms of the operation. In this form of Suggestion,

which is far more common than is generally imagined, diplomats, women, and others having fine perceptions and instinctive delicacy of mental touch, excel. The lift of an eyebrow; the shrug of a shoulder; the carefully shaded accent—all these are phases of this form of Suggestion. And many little tricks of manner, gesture, etc., are likewise. So common is the use of Suggestion in these times, that an acquaintance with the subject is almost absolutely necessary to every one.

Another form of Suggestion that has sprung into prominence in late years, is that of Therapeutic Suggestion, by which term is meant the employment of Direct Suggestion for the purpose of causing the mind to exert its inherent power to regulate the functions of the body, by means of the involuntary nervous system, etc. Therapeutic Suggestion has reached an important place in the method of combating disease and ill-health, and is now taught in all the principal medical colleges, although until recently regarded by them with disfavor. It also covers and explains many of the various forms of "healing" by various mental and so-called "spiritual" methods, which, under various guises and names, have

grown so rapidly in popular favor during the past decade. A portion of this book shall be devoted to this branch of the subject.

Another important branch of the general subject of Suggestion is found in what is known as "Auto-Suggestion," which is Self-Suggestion, or Suggestion given by oneself, to oneself, according to certain methods and principles, and which method is also in great favor at the present time, under one name or another, and under one theory or another. Auto-Suggestion may be, and is, advantageously employed along therapeutic lines, and many cases of "healing" by many supposed methods, are really the result of the auto-suggestion of the patient, aroused in various ways. Auto-Suggestion is also very advantageously employed in Character Building, and in Self Development. It is found to be the active basis of all the various forms of self improvement along mental lines.

All of the above forms of Suggestion will be touched upon under the chapters devoted to them in this book, with further explanation and details. The purpose of this introductory chapter is merely to give you a general idea of what Suggestion *is*, and its several forms.

CHAPTER II.

SUGGESTION OF AUTHORITY.

In the preceding chapter we called your attention to the fact that Suggestions are accepted by persons when given by one or more of three general methods. These three methods, you will remember, are: (1) Suggestion by impression, as by authoritative statements, etc.; (2) Suggestion by inducing the idea in the mind, by insinuation, hint, and other indirect means; and (3) Suggestion along the lines of association of outward objects, etc., which act both by impressing and inducing the idea in the receptive mind of the person so suggested to.

But these three classes of suggestion may be considered as being caused by the suggestion reaching the individual along several different lines, or channels. For convenience we may divide these channels of suggestion into five classes, viz:

I. The Suggestion of Authority;

II. The Suggestion of Association;

III. The Suggestion of Habit;
IV. The Suggestion of Repetition;
V. The Suggestion of Imitation.

In order that you may be able to distinguish the difference between these different phases of Suggestion, we shall call your attention to the details observable in each, briefly and concisely, that we may hasten on to the general subject of the book.

I. *The Suggestion of Authority*: This form of suggestion manifests along both the lines of impression and induction, respectively. That is to say, Suggestion by Authority manifests both in the positive authoritative statements directed to the point; and also by the spoken or written statements made by those who speak or write with an air of authority. It is a peculiarity of the human mind that it is inclined to listen with respect and credence to the words, written or spoken, of persons who assume the air of authority and knowledge. The same person who will weigh carefully every proposition of those whom he considers to be his equals, or inferiors, will accept the statements of those whom he considers to possess authority or knowledge exceeding his

own, without more than a casual questioning, and sometimes without any questioning or doubt whatsoever. Let some person posing as an authority, or occupying a position of command, calmly state a fallacy with an air of wisdom and conviction, without any "ifs" or "buts," and many otherwise careful people will accept the suggestion without question; and unless they are afterward forced to analyze it by the light of reason, they will let this seed idea find lodgment in their minds, to blossom and bear fruit thereafter. The explanation is that in such cases the person suspends the critical attention which is usually interposed by the attentive will, and allows the idea to enter his mental castle unchallenged, thereafter to dwell at home there, and to influence other ideas in the future. It is like a man assuming a lordly air and marching past the watchman at the gate of the mental fortress, where the ordinary visitor is challenged and severely scrutinized; his credentials examined; and the mark of approval placed upon him before he may enter.

The acceptance of such suggestions is akin to a person bolting a particle of food, instead

of masticating it. As a rule we bolt many a bit of mental provender, owing to its stamp of real or pretended authority. And many persons understanding this phase of suggestion, take advantage of it, and "use it in their business" accordingly. The confidence-man, as well as the shrewd politician and the seller of neatly printed gold mines, imposes himself upon the public by means of an air of authority, or by what is known in the parlance of the busy streets, as "putting up a good front." Some men are all "front," and have nothing behind their authoritative air—but that authoritative air provides them with a living. As Bulwer-Lytton makes one of his characters say: "Whenever you are about to utter something astonishingly false, always begin with, 'It is an acknowledged fact,' etc." Many a false statement has been accepted when prefaced with a "I assert without fear of contradiction," etc. Or, "It is generally conceded by the best authorities, that," etc. Or, "The best sources of information agree," etc. Often there is this variation: "As you probably know, sir," etc. But in many cases there is not even this preface—the statement is made

with a "Thus saith the Lord" manner, and is accepted because of the tone and manner accompanying it. As a rule these authoritative suggestions are not accompanied by argument or logical proof—they are thrust at you as self-evident truths. Or, if argument there be, it is generally but a few specious comparisons of bits of sophistry, offered to quiet the mental conscience of the person. Many authoritative suggestions are crystallized into epigrammatic axiomic phrases, which are accepted as true because of their "patness," and apparent smartness, without analysis on the part of those to whom they are offered. Political catch-words, and current explanations belong to this class. Many a phrase is accepted by the public because it "sounds good," without any regard to the truth stated in it.

It would not be so bad if it were merely the acceptance of the suggestion of authority in itself. But that is only the beginning of the trouble, for the suggested idea once admitted to the mind without question takes up its abode there and colors all subsequent thought of the individual. Many of us have experienced periods in our life, when, some new idea

attracting us, we found it necessary to take mental stock of our other ideas on the subject. In such cases the majority of us have found that our minds have been filled with all sorts of mental rubbish, without any basis in actual truth, which have been acquired in the past merely from the acceptance of the suggestions of authority. We are like the man of whom Josh Billings once said: "He knows more that hain't so, than any other man a livin'." We advise you to be a little less hospitable to these authoritative statements in the future. Be a little bit more your own authority. If you find it easier to accept a strong statement of this kind, at the time, do so with the mental reservation of "accepted subject to future examination, with privilege of rejection." And above everything else in this line, be sure of the "authority" of your stater of facts—examine his credentials.

II. *The Suggestion of Association*: This form of Suggestion is one of the most common phases. It is found on all sides, and at all times. The mental law of association makes it very easy for us to associate certain things with certain other things, and we will find that

when one of the things is recalled it will bring with it its associated impressions. For example to many persons the odor of certain flowers recalls the memory and feelings of funerals, cemeteries and death. This because at some time the person has perceived the identical odor when associated with the scenes of a funeral. The faint odor of mignonette will carry the mind back over the years to some tender episode of the earlier days, and before we know it we are indulging in sentimental reminiscences and thoughts of "it might have been" and all the rest of it. The sound of some old melody will bring back the feelings, sad or joyful, of time long since past. We know of a case in which the individual has a chain of melodies reaching back for many years, each particular one being connected with some particular period of his life. When he wishes to live over the past, he begins humming, and thus travels from youth to middle-age, or the reverse, by the sound of the various melodies.

But there are many other forms of suggestion by association. We are apt to associate a well-dressed man, of commanding carriage,

traveling in an expensive automobile, as a man of wealth and influence. And, accordingly when some adventurer of the "J. Rufus Wallingford" type travels our way, clad in sumptuous apparel, with the air of an Astorbilt, and a $10,000 (hired) automobile, we hasten to place our money and valuables in his keeping, and esteem ourselves honored by having been accorded the privilege. The actor, orator, preacher and politician use the suggestion of association upon us by the employment of tones vibrant with feeling and emotion, which are associated in our minds with the actual feeling and emotion—and lo! we are weeping or laughing; smiling or frowning; filled with approval or condemnation, as the case may be. The speaker pulls the associative strings of suggestion, and we dance accordingly.

We find that many of our prejudices, favorable or unfavorable, are the result of associations of past experiences. If we have had an unpleasant business experience with a man with a peculiar expression or color of hair, we find it hard to overcome a prejudice against others of similar personal appearance, in after

years. Sometimes a name will carry associations with it. We once knew a man who would absolutely refuse to have business dealings with any one named "M——," because he had once been badly worsted and cheated in a real estate deal by a man of that name. Many names are associated with persons who had borne them in the past, and, as ridiculous as it may seem, we find it difficult to overcome the prejudice. The majority of people have experiences of this kind.

How many of our readers do not feel an antipathy for some particular article of food, because of some unpleasant experience with that article in the past? Personally, when the writer was a boy, his father wishing to break him of the habit of eating too heartily of "cream-puffs," once offered to pay for all that the boy could eat at one time. Boy-like, the offer was accepted, and the result was disastrous—for years after he could not look at a cream-puff without feeling sad and reminiscent. And the memory of what he once found in a hotel mince-pie, caused an associated suggestion that held its grip with the passage of the years.

How many of our ideas are the result of associated suggestion, we can tell only when we begin to take occasional mental stock. Many of our ideas, feelings, prejudices, likes and dislikes, are the result of this form of suggestion, rather than of anything really attaching to them alone. The moral is that we should watch carefully the company that our mental images are keeping, and avoid unpleasant mental attachments.

CHAPTER III.

SUGGESTION OF HABIT AND REPETITION.

III. *The Suggestion of Habit:* This form of Suggestion is closely allied to the preceding phase, i. e. Suggestion of Association, in fact, some consider it to be merely a branch of the latter. But we feel that there is a decided difference in the operation of the two phases, and accordingly prefer to treat this one as forming a separate and distinct phase. Of course, all habit is an association with something in the past, but Suggestion of Habit may arise from an original cause of Suggestion of Authority; Suggestion of Association; Suggestion of Repetition; Suggestion of Imitation; or else from an original decision of the intellect resulting from correct reasoning. The suggestive feature of Suggestion of Habit arises not from the nature of its original cause, but from the fact that the previous action or thought acts as a suggestion for the act or thought of the present. The former act or thought acts as a sugges-

tive "outside influence," although it belongs to one's own mentality.

It is astonishing to many of us, when occasionally we are brought to a realization of the degree of habit-action and habit-thought that has been developed within us. We do things simply because we have done them before, notwithstanding the fact that the circumstances of the case have altered materially; we think thoughts, and hold opinions, simply because we have thought so in the past, although the circumstances may have altered materially. We get into a jog-trot of habit—we fall into the rut of routine—and lose initiative thereby. The Suggestion of Habit is strong with the majority of us.

There is a very good excuse for this development of the Suggestion of Habit, for the majority of our daily actions and activities are possible only through having "learned them by heart." In order to perform our tasks we must have first learned them consciously, and with much expenditure of concentrated attention; and then, having learned them, we have passed them over to the "habit-mind" of the subconsciousness, that they thereafter be per-

formed automatically, and thus easily. The New Psychology recognizes the important part played by habit in mental operations and physical activities, and therefore urges its students to cultivate the habits which will be beneficial to them, and to inhibit those which may prove detrimental. And it is in this same spirit that we are now calling your attention to the effect of the Suggestion of Habit. We are not advising that you do away with habit —but that you select good habits of thought and action, and then trust to them.

The mind of man is plastic, particularly in youth, the period in which the majority of our mental and physical habits are formed. As Romanes well states:

"No change in childhood's early day,
No storm that raged, no thought that ran,
But leaves a track upon the clay,
Which slowly hardens into man."

In our book on "The New Psychology" we have given directions whereby habits may be cultivated, restrained or inhibited, which we shall not repeat here. The realization of the effect of Suggestion of Habit will call your attention to the need of taking account of the

same, in the direction of restraint and improvement.

To realize the force of habit, try the following simple tests: Try to put on "the other shoe" first, in the morning. Each of us has the habit of putting on first one particular shoe, in preference to the other. Change to the other shoe, and you will find it awkward, and for some time afterward you will have a subconscious feeling that something is wrong, or has been forgotten. Or, try to put "the other arm" in your coat-sleeve first—each of us has a certain way of putting on a coat, the same arm first each time; and if a change is made the utmost awkwardness is manifested. Each of us gets out of bed on one particular side, and we dress according to rule, in the same way. Try the experiment of putting on a stocking, and then put on the shoe of the same foot instead of proceeding to draw on the second stocking, and see how "mixed up" you will feel. The older we become the more we are apt to become set in our habits of action and thought. We accept the Suggestion of Habit, instead of using initiative, or original thought.

How many people are Republicans or Democrats, as the case may be, simply because they started out so—without regard to any new issues, or local question. They may make high resolves to "do something," but when the election day comes around they fall in line like well drilled soldiers. Many of us belong to certain churches for the same reason—we have just "gotten into the habit of it," and no attraction can lure us to pastures new. We cross the streets at certain corners, on our way home—just because we started out that way. And we hold certain fixed ideas, not because of any special truth or merit in them, but simply because we once accepted some suggestion or statement along the same lines, and thenceforth adopted it as our own, and now "swear by it" as if we had thought it out carefully and intelligently. In fact the ideas that we fight the hardest for are very apt to be those which we have made our own by the Suggestion of Habit rather than those which we have thought out carefully. Bigotry and intolerance, "narrow-mindedness" and mental stubbornness arise largely from this Suggestion of Habit. Sug-

gestion of Habit does not allow the person to see any "other side" of a question. His subconsciousness has the fixed idea firmly impressed upon it, from habit, and it requires a mighty wrench to dislodge and cast out the record. The majority of our ideas are the result of this form of Suggestion. This being so, it is well for us to take mental stock occasionally, and apply the test of present knowledge and reason to our "inmost convictions," the majority of which we would not think of accepting today, were they presented to us as new propositions to be examined and judged by the reason.

IV. *The Suggestion of Repetition*: This form of Suggestion may seem to be very much akin to the preceding phase, i. e. Suggestion of Habit. But there is a marked distinction and difference. Suggestion of Habit has its power imparted to it by the habitual repetition of the act or thought on the part of the individual; while Suggestion of Repetition gains its power and force by the repetition of a Suggestion from some outside object or person. It is an axiom of Suggestion that: "Suggestion gains force by repetition." A Suggestion of but

moderate impressive or penetrative power in the first instance, gains force and power at each repetition. It is the old story of the repeated blows of the hammer driving in the nail; or the constant dripping of water wearing away the stone. A Suggestion which passes you without much attention or consideration, when first made, will gain both attention and consideration from you if it be repeated sufficiently often, and in the right manner. Repeated Suggestion tends to break down the instinctive powers of resistance in a person, unless the person realizes that it is a Suggestion and thereupon interposes an obstacle to the impression.

Many things that you accept as beyond question have been impressed upon you by the force of repetition. You hear a thing on all sides, and although you may have no knowledge or proof of it, still you are affected by it, and gradually grow to accept it as at least a presumptive fact. Repeated "they say" has ruined the reputation of many a person. A repeated statement or claim of fact often obtains credence without possessing any basis in truth. Many utterly foolish superstitions

and ridiculous "notions" have become current because of repetition. The whole matter is understood when one begins to understand the nature of the subconscious mind, and the region of the memory. In these regions of the mind there is preserved a mental record or impression of each thing that comes to the attention of the person. And these impression-records are strengthened by each repetition of the thing. The realization of this law gives us the key to the development of the memory, and also to the understanding of Suggestion of Repetition. The process and the rule is the same in both cases.

If you wish to impress a thing upon the records of your memory, you know that repetition is one of the most effective methods. Each impression of the die of attention deepens the original record-impression. And in Suggestion of Repetition, each time the Suggestion is made and accepted, the record-impression is made deeper. You have heard the old story of the person who told the tale so often that he grew to believe it himself, have you not? Well, this idea of Suggestion of Repetition is along the same lines. You hear

a thing so often that you get to believe it yourself—its repetition giving to it an air and appearance of validity, and causing you to involuntarily imagine that you have always believed it. Who has not known persons who vigorously combated certain ideas in the beginning, and who afterward yielded to the insistent repeated suggestions of others regarding the thing, until he accepted them and finally asserted that he had "always so held."

Many a shrewd judge of human nature, along the lines of salesmanship and advertising, understand this law of Suggestion of Repetition. They will artfully manage to get in repeated suggestions, by presenting the same statements in different terms, or else by a flat repetition of an authoritative statement, until you forget the beginning, and the idea grows to be an old story with you, and one that you never seem to question. We have heard of a politician of national renown, who once said: "Proof? We don't *need* proof! Tell the public a thing solemnly, and authoritatively, and *repeat it sufficiently often,* and you will never need to *prove* anything!" Repetition, like Pretended Authority are two old frauds

masquerading as Truth. When you once take their measure, you have disarmed them so far as you are concerned. When you call for "Proof," they take refuge in dignity and reiteration—that is their entire stock in trade. But Suggestion of Repetition has its value in imparting Truth. It is a poor rule that won't work both ways.

CHAPTER IV.

SUGGESTION OF IMITATION.

V. *The Suggestion of Imitation*: This form of Suggestion while being in itself a distinct phase of Suggestion, nevertheless has a very close relationship with the several other forms of Suggestion. In the acceptance of Suggestion of Authority there is to be found an unconscious imitation of the mental attitude of the person asserting the authority; in Suggestion of Association there is an imitation of the associated thing; and in Suggestion of Repetition there is to be found evidences of imitation. But still, Suggestion of Imitation forms a distinct phase of Suggestion, in itself.

Man is an imitative animal. There is to be found in the human race a decided degree of the faculty of imitation which plays such an important part in the lives of our cousins the apes and monkeys. Many persons who would resent any such comparison, nevertheless evince a constant desire to imitate and follow

the actions, thoughts and appearance of those around them. Individuality is a far more rare thing than is generally imagined. In fact, let a man show individuality of taste and action, and he is looked upon as "queer," and is avoided as "out of the ordinary" by the majority of people—unless he is sufficiently strong to force his ideas upon the crowd and thus set the fashion. We live in an era of imitation, notwithstanding our claims of individuality. Our civilization demands that we wear the same cut of clothing; the same width of hat-brim; the same kind of hair-cut, and the same color of neckwear—under the penalty of being called "eccentric."

We copy the attitudes, appearance, tones, and little personal peculiarities of some prominent person, seemingly imagining that by so doing we may absorb his qualities. We think the thoughts of others, and share their ideas, according to the same law of Suggestive Imitation. Ideas, as well as clothes, have their fashion. Our churches and our playhouses fall in line with the examples set them by others who have caught the public notice. There is very little room for the individual

who prefers his own ways to those of the leaders of fashion who set the public example—it is "get in line, or get out." Some actress wears a new gown of a striking cut, color, or trimming, and the world of womankind falls in line. Sometimes it is fashionable to be "plump;" sometimes the style changes to the *svelte* willowness of the Directoire gown. The dressmakers and milliners of Paris deliberately coin new styles in order that there may be a demand for the new articles among those who follow the fashions, and the remainder of the people are gradually forced into an acceptance of the arbitrary styles.

A new monarch causes a complete change in the accepted styles of walk, carriage, and personal peculiarities; and even in republics the same thing is being manifested, each president causing a manifestation of the desire to follow the lead in the way of exercise, personalities, etc. An era of calm dignity is followed by an era of strenuousness—an epoch of tennis is followed by one of golf, according to the tastes of the respective leaders. Philosophies, theories, schools of thought and branches of religious denomination are accepted because they are fashionable.

The old trick of the practical joker illustrates Suggestion of Imitation. The joker pauses on a crowded thoroughfare, and gazes intently at an imagined something up in the air, or else on the roof of a sky-scraper. In a few moments others stop and gaze upward; then others; and so on until the policemen come to disperse the crowd. We follow the motion of a tight rope walker, swaying in unison with him. We imitate the facial expression of the actor on the stage, frowning or smiling as he does. We catch ourselves imitating the walk or physical motions of persons in whose company we are, and there are but few persons who are immune to the intonation or "brogue" of those with whom they associate. The New Englander falls into the localisms and accent of the West or South if he lives there for a time. The Southerner loses his soft accent when he lives away from home, and is only aware of the change in himself when he happens to return home for a visit, when his folks notice how "Yankeefied" he has become, and he notices the extreme Southern accent among his friends and relatives.

We have a personal knowledge of a young physician, of English-Scotch ancestry (not a drop of German blood in his veins) who spent several years in Germany in the universities and hospitals. When he returned to America he was a German in accent, habits, appearance and tastes. So marked was the change, that he finally settled in a German quarter of the town in which he lived, and practiced exclusively among Germans and persons of German descent, preferring their company and customs, and fitting closely into their requirements and preferences. Contrast the children of foreign parents in this country—see how different they are from their parents in every way. Sometimes the change is an improvement—and sometimes it is a throwing away of the good old qualities and an acquiring of the new objectionable ones. Environment plays a very important part in our lives. And Environment is largely the effect of Suggestion of Imitation—that tendency of the race to level itself up or down; to get into line; to be in the fashion.

Have you ever noticed the contagiousness of mental states, or actions, as evidenced in

the daily press. Let there be an elopement, and immediately there are many others of the same kind. Crimes repeat themselves in the same way, even to details. Suicides are suggested in many cases by reading public prints. This fact is recognized by psychologists, and an effort is being made to prohibit the rehearsal in the newspapers of objectionable occurrences. The cheap moving picture shows have come under the supervision of the authorities, because of this fact of Suggestion of Imitation. Young people seeing crimes and other immoralities exhibited in the pictures, display a tendency to imitate them. The stage has a marked effect upon the morals of the people, not in the way of "instruction" as many assume, but in the way of Suggestion by Imitation. This form of Suggestion is attracting much notice from students of sociology and civic progress, and is bound to come to the front during the next ten years. The public has the tendency to follow the suggestions of the things presented to its notice. The remedy is suggested in the evil itself. If undesirable things are imitated, then counteract the evil by prohibiting the same as far as is

possible, and neutralize it by presenting the desirable things to the attention in an attractive way.

The phase of Suggestion of Imitation, connected with the health of the people, is also receiving marked attention from the authorities and moulders of public opinion of late. It is recognized that the printing of the advertisements and "literature" of certain patent medicines and other remedies is calculated to react upon the health of the public. These advertisements with their recital of "symptoms," including every possible known physical and mental "feeling," sensation, ache or pain, undoubtedly impress many people with fear and imaginary complaints. This would be bad enough in itself, but is rendered doubly evil by the fact that these imaginary complaints have a tendency to materialize into actual physical troubles, by the effect of Therapeutic Suggestion. Thought tends to take form in action; and Mental Pictures tend to become real in the physical realm. Fear in itself is a powerful depressant, bound to react upon the physical functions and to impair the physical well-being of the person manifesting

it. A community may enjoy a very good health record; but flood it with objectionable advertisements and printed matter containing a recital of "symptoms," illustrated with pictures of diseased organs, and in a short time there will be more cases of sickness in the place than ever before in its history. These are proven scientific facts, known to every student of the subject. The moral is obvious.

You will find that the instances of Suggestion of Imitation are far more common, and far greater in number, than those of any of the other forms of Suggestion. This is because the causes operating along these lines are far more common and numerous. There is ever present a great supply of the "raw material" for Suggestion of this kind. The tendency of the race to "get into line;" to "follow my leader;" to act like human sheep or geese makes it easy for them to fall into the habit of accepting these suggestions. You have heard of the custom of sheep to follow the actions of the leader. It is said that if the leader jumps over a rail of a fence, the rest of the flock will follow; and if the rail be removed,

the rest of the flock will continue jumping over the place where the rail had been.

In this phase of Suggestion, as well as the others previously mentioned, there is of course the reverse side of the question to be considered. We have shown you how easily people are affected to their detriment, and to the advantage of others who influence them. But it is equally true, and much more worthy of the race, that people may also be influenced for good in the same way. The Suggestion of Authority has its advantageous side, for in this way a worthy strong person or body of people may impose the knowledge of good upon those not so well informed—the crowd will accept it by reason of authority, before their reasons can grasp the "why" of it. In the same way Suggestion by Association may operate for good, providing the associations are desirable. And Suggestion of Habit, and Suggestion of Repetition may become great sources of right action, providing the moving cause is good. And so, Suggestion of Imitation becomes a mighty power for righteousness in the hands of the right persons, and when conducted along the right lines. Those

who set good examples, and fashions, influence people just as do those who are at the opposite pole of precept. Good health is just as contagious as disease. When Suggestion of Imitation is well understood by the public generally, there will be a demand for the suppression of the things giving the hurtful suggestions, and for the encouragement and advancement of those setting good examples, and furnishing the right kind of suggestions. The remedy is plain—it is for the people to use it.

CHAPTER V.

INSTANCES OF SUGGESTION.

In looking around about us for the purpose of gathering instances of typical forms of Suggestion, we are embarrassed by a wealth of material. Instead of having to hunt for such instances, we rather find it difficult to escape the numerous instances of the use of Suggestion which insistently push themselves upon us from all directions. Suggestion is such an active motive principle of human conduct that we find ourselves unable to escape from evidences of its operation, when once we have had our attention directed to the subject. We pick up the morning paper, and there we see hundreds of instances which will work their suggestive influences, for good or evil, upon the minds of those who read them. Here is related the example of some man who has given his life for humanity—and someone will accept the suggestion, and his life will be influenced by the example of this man. Here is related the thieving achievements of some

shrewd hierophant of "Frenzied Finance," whose example will be noted and acted upon by some of its readers. Here is the recital of a crime, suicide, or scandal, which will plant its suggestive seed in some congenial soil, there to grow into action. Here is some inspiring bit of news, which sends a suggestive thrill through us, and nerves us to higher and better effort in the day's work. Here is some depressing item of news, calculated to hatch forth pessimistic thought and philosophies in some mind ready for the suggestion. Here is the speech of some world-worker, in which is a wealth of inspiring and stimulating suggestion—and next to it is the reverse. And so it goes, each seed suggestion being extremely likely to find lodgment in the receptive mind of persons in harmony with the respective idea.

And turning to the advertising pages, we find the same thing repeated. The virtues of certain brands of Baby Foods, or Pain Killers are fastened upon our minds by suggestive notices based upon the principles of Suggestion of Authority or Repetition, respectively. We are told that "Uneeda Biscuit;" or that

"Ivory Soap Floats;" or that "Puffed Rice is Shot From Guns;" or that "Babies Cry for Castoria;" or that "Somebody's Whisky is Smooth;" or that "Puffer's Cigars are Fragrant;" or that "Pilkin's Purple Pills Will Cure that Tired Feeling;" and so on.

Leaving our homes and entering the street-cars, elevated trains or suburban expresses, as the case may be, we find ourselves confronted with startling signs extolling the wares of various manufactures, each containing some shrewdly worded phrase, telling us either *to do something* or else that *a certain thing is true,* in both instances the statement being connected with certain articles of merchandise. We gaze upon cleverly drawn pictures of men arrayed in nicely fitting coats or neat hats, and involuntarily contrast our old clothes or hats with the pictured elegance, and thereby set into operation a train of thought which sooner or later leads us to invest in some of the articles in question. These advertisements seek first to arouse desire within us, and then to drive it home and transform thought into action, by Suggestion of Repetition.

Leaving our car we find the store windows filled with a suggestive display of attractive things, calculated to arouse desire for possession within our minds. The art of window-display is first to attract the attention by the artistic appearance of the display; and then to arouse desire within us by the quality and appearance of the goods, with a subtle appeal to our bargain instinct by a display of low prices "specially marked down for the Washington's Birthday Clearing Sale." From first to last it is this effort to arouse attention, and to create desire. Look at the crowd of women clustered around the shop windows, gazing longingly upon some attractive display of clothing or hats, or the thousand and one other things so dear to the feminine heart. Don't you realize that out of that crowd there will be some whose "want to" will be so vigorously aroused, that the suggestive seed-idea will be sure to blossom into active "must have it" in a day or so?

There are schools for advertising, which carefully instruct their pupils in the laws of psychology in this matter of attracting attention and arousing desire. Do not suppose for

a moment that this clever advertising "just happens" to catch your eye, and arouse your desire—not a bit of it. These skilled advertisers, who are paid very large salaries, have been carefully trained in the laws of suggestion, and they put their knowledge into practice every day of the week, with a little extra touch on Sunday. There is one man employed by a large advertising agency in New York and Chicago (he spends part of his time each week in each city, traveling on fast limited trains at night in order to lose no time) who is paid a salary reputed to be equal to that of the President of the United States. And his work, and the value of the same, is along the line of the most clever employment of suggestive words, display, and presentation of the advertisements of the various customers of that agency. Did you think that you bought a certain article because you were convinced from careful examination that it was just what you needed? Nonsense! You bought it because the scientific advertiser had exerted his suggestive art upon you, first by attracting your attention by a striking display of his advertisements, and then by the insistent,

and repeated epigrammatic statements regarding the fact that you, yes *you,* needed that particular article. Reason, indeed! You were suggested into it by a series of suggestive pictures and clever phrases. Of course the article is good, and you got your money's worth, but that does not alter the principle.

Then you go into a store, or else a salesman calls at your office. Some of these salesmen, or saleswomen, repel you and you do not care to deal with them. Others have a "winning way" about them, and before long you are placing your orders. Did you suppose that it was just because these salespeople were pleasant, intelligent and courteous? Dear me, you are far behind the times. Of course a pleasant manner, intelligence, and a desire to please have great value in salesmanship, and will always reap their reward in orders and pleased customers—but even this is not always the result of natural inclination, and even if it is, there is more to the thing than that. Do you know that there are numerous schools of salesmanship springing up in all parts of the country, instructing the students in—what do you suppose? In the Psychology of Salesmanship!

Teaching them the psychological laws that are to be found in every sale—teaching them the nature and value of Suggestion in selling goods. And not only this, but many of the large concerns employing solicitors have private courses in salesmanship, in which their salesmen arecarefully drilled and trained how to approach people properly; how to present their proposition; how to meet objections; and *how to use Suggestion.* The modern business man has received his education in psychology, and is applying it in his every-day business. We are not objecting to this—personally, we would rather deal with a trained salesman than with a clumsy, untrained, "raw" recruit. We are merely calling your attention to the important part played by Suggestion in every-day business life.

Your day's business takes you into a court room, and lo! you find Suggestion there. You see a witness on the stand, in the hands of a clever lawyer who is drawing out the desired information by a clever line of suggestive questionings. The much decried "leading questions" of the lawyers, which are subject to objection from the opposing side, are but

forms of Suggestion. The up-to-date lawyer does not need to use the "leading question"—instead he subtly starts certain trains of thought in the mind of the witness, by accenting certain words, etc., and thus accomplishes the same end. Listening to a clever cross-examination by an expert is equal to a preliminary course in Suggestion. And then, you will find an employment of Suggestion in the address of counsel to the jury. A sentimental association is aroused by a reference to something likely to have been experienced by some of the jurymen; prejudices are aroused by suggestion and insinuation; doubt is cast on the statements of opposing witness by a subtle tone and expression, where words would have aroused suspicion. And so on to the end. And even in the judge's charge unconscious suggestion is used, although many judges will indignantly deny this fact. If a judge inclines toward a certain side of a case, by reason of his own prejudices or conviction, he will often unconsciously impart that leaning by suggestion in his charge. This all jurymen know, and they will tell you that in some way they became impressed with the true beliefs of the

judge, even although the charge was delivered in a most impartial manner with carefully chosen words. The Suggestion was manifested in the *emphasis* unconsciously placed upon certain facts or words. And, if the case goes to a higher court, on appeal, this suggestive accent or emphasis is missing from the printed words, "if" and "but," which turned the scale in the jury-box.

After the day's work, you start to return home, when you are confronted with a big blinking electric sign, telling you to "Take Home a Box of Riler's Chocolates for Your Wife!" And of course you do. Over the coffee, at dinner, your wife innocently informs you that your best friend has presented his wife with a new set of furs that are *so* becoming; and she wonders if the friend is not an exceptionally able business man to be able to be so liberal; and then he is *so* kind and thoughtful of his wife and family. Thus is the "fur" seed suggestively planted in good rich soil—never fear, it will be well watered with tears, and watched with shy, loving glances, until it blossoms into realization a little later on.

And that night, in your sleep, you will dream of something connected with business that will suggest something else that will have an effect on your actions the next day in your business. You can not escape Suggestion, even in sleep.

CHAPTER VI.

SUGGESTION IN BUSINESS.

In the preceding chapter we called your attention to the fact that Suggestion is now recognized in the affairs of every-day business life, and that instruction along its lines is now given to those aspiring to reach the attention of the public. Business psychology has come to stay, and it has worked a revolution in many branches of commercial life. Appeals to the public mind are no longer made in a haphazard, hit or miss manner, but along certain well established methods of attracting and holding the public attention, to the end that desire may be aroused and demand created for the wares of the sellers.

Especially is the above so with regard to salesmanship and advertising. It is a fact not generally recognized, that advertising is merely one form of salesmanship—selling at long range. And accordingly the "selling talk" of the salesman and the "selling talk" of the advertisement must be based upon the

same principles. This fact is recognized by all of the live advertisers and salesmen, and improvement along the lines of selling Suggestion is being made constantly.

In the training of salesmen, there is a constant reference to Suggestion in all of its forms. The embryo salesman is instructed in what is called the "Pre-Approach," by which is meant the general self-training of the salesman, along the lines of Auto-Suggestion, to the end that he may get himself into the proper frame of mind to impress the customer in the best way. The salesman is instructed to fill himself with the idea of the value of the goods he is to offer the customer; the fact that these goods are just what the latter needs and should have in his business; the fact that instead of asking a favor of the customer, the salesman is really doing him a good turn in calling his attention to them—in short, the missionary spirit with its burning zeal for "conversion" is inculcated in the salesman, so that he becomes an enthusiastic advocate instead of a mere "seller of goods." If the instruction in Suggestion went no further than this, it would be a valuable addition to

the qualities of the salesman—but it goes far beyond this point.

The next stage in the instruction of the salesman is what is called "The Approach," by which is meant the manner in which the prospective customer should be approached. The salesman is instructed to carry himself in such a way as to suggest Self-Respect; and to dress in such a way as to suggest business standing and prosperity, avoiding shabbiness on the one hand, and over-display on the other. He is taught to maintain a cheerful, optimistic state of mind, for this suggests itself in his outward appearance and manner and produces a much better effect on the customer than would a surly, crabbed, pessimistic manner. Then follows the proper method of introducing oneself, and one's business, to the customer, according to the character of the latter. One of the largest selling concerns in the country, in its little manual for the use of its salesmen, says: "The first five minutes of speaking to a man is likely to make or break you as far as that sale is concerned. If you are in any way antagonistic or offensive to him, you have hurt your chances badly from

the start. If you have failed to definitely please or attract him, you have not done enough."

Then follow instructions regarding the psychological elements of a sale. First comes Attention—this is the first point in the sale, and the salesman must secure it, or else he can proceed no further. Then follows the stage of Curiosity, or Interest, in which the salesman is taught to arouse the former and gain the latter. Interest must be aroused before desire may be awakened. To arouse interest the business proposition, or article of sale, must be presented in an interesting manner, with well chosen and properly delivered words. This point secured, the salesman is instructed in the science of arousing Desire, for in this lies the motive power which leads to sales. The customer must be made to "want" the thing before he will purchase it. Then he must be made to realize that he can afford to buy it. The price is held back until the psychological moment, and then is introduced in a casual way, with little or no emphasis on the amount—just a suggestion that such and such a price is attached to the thing—sort of a side

affair, after all. Then comes the point of closing the sale, and obtaining the order or signature. This is the aim and goal of the entire process, and many are the points of instruction imparted regarding this closing. The signing of the order is suggested by pointing to the proper line with the suggestion: "Sign *here,* please;" some going so far as to suggest the action by handing the customer a fountain pen, slanted at the "suggestive angle."

The prospective salesman is trained to recognize the various mental traits predominant in the customer, and methods are supplied whereby these qualities may be appealed to properly. His vanity, pride, covetousness, social aspirations, jealousy, desire for success, desire for advancement, desire for self-improvement—all these are recognized and have their appropriate suggestions. The Imagination is considered, and the salesman is taught how to paint word pictures for it. Salesmanship is indeed a science and an art, in these days, and they are "getting it down finer" every day.

Clerks in retail stores are instructed to have

their customers seated, in order that the standing salesman may have the advantage of the "suggestive position." They are also trained to use the "suggestive question," such as "This is a very beautiful shade, *isn't it?*" or "This will make up well, *will it not?*"—the customer's answer being directly suggested to him, or her, in the first part of the question, which consists of a positive statement followed by a question asking for corroboration. It is much easier to say "Yes!" than "No!" to such a question—*isn't it?* The saleswoman who shows her customer an article a little higher in price than one which is being examined, with the remark: "Now here is something *very* much better. Of course it costs a little more but it is well worth the difference, *but of course, etc.*"—the implied suggestion of the "of course," to the effect that the customer might not wish to exceed the lower price, often acting to put the woman on her mettle, and she buys the higher-priced thing just to show that she is "able to" do so. To the wealthier customers, the suggestion is always of quality, style, exclusiveness, etc., while to the poorer it is always "price," "bargains"

and the rest of it. The salesman or saleswoman who understands human nature and Suggestion, will make much larger sales than those who are lacking in this infomation.

The business of window dressing, display, marking prices, etc., makes a liberal use of Suggestion. Models are tastefully dressed in the windows, and the women gazing therein receive the suggestion that they too would look that way, if they wore the same goods. The beautifully formed living model is used to "try on" coats, in the cloak department, that the woman customer may see "just how it will *look on you.*" In the millinery department, the young woman upon whom any hat looks stylish is used to try on the various hats, that the customer may see "how they will look." All this is Suggestion pure and simple—the Suggestion of Association. "Bargain Sales," and "Marked Down" articles are attractive suggestions. "97 cents, marked down from $1.00," suggests a great saving. $4.98 seems so much cheaper than $5.00. Odds and ends of trimmings, unwound and mussed up in a heap on a "Bargain Table" suggest great bargains. The Psychology of the Department Store is a study in Suggestion.

In advertising, the same employment of Suggestion is made. There is the "Direct Command," or Suggestion of Authority which tells you to *do* certain things at once; or to buy certain things for certain reasons. There is the suggestion of taste and flavor in advertisements of eatables and drinkables. "Delicious," "fragrant," "luscious," "sweet," "mild," "invigorating," these and similar words suggest taste, or smell to the reader. Read the advertising columns of the daily newspaper, or the advertising section of the current magazines, in the light of what we have said, and see the ingenious uses of Suggestion. Read the signs in the store windows, or over their doors, and see the part played by Suggestion. "The Store of Quality;" "The Home of Bargains;" etc.,—these are suggestions.

A writer in the magazine "Salesmanship" says: "To make advertising which will sell goods requires development of the human part of the writer. He must realize the different forces which command Attention, Interest, Desire and Conviction." You see then, advertising is salesmanship at long range. The

same principles are involved. The same writer says: "The fact is that salesmanship and advertising are practically synonymous terms. A good ad. man must be a good salesman. The only difference lies in the fact that the salesman meets the customer personally, and the ad. man sends him a message in type. The same argument, the same tact, and the same persistence must be present. It takes more brains to sell the goods than it does to make them; you can steal them, but to sell them is an Art." A writer in a magazine devoted to advertising, says: "Really clever ad. writing goes far and away back of, and deeper than, the smartness of phraseology that men like to pay for. . . . Advertising takes into account the subconscious impressions, the varying phases of suggestion and association as received through the eye, the psychology of the direct command,—all worth earnest consideration, and seriously to be reckoned with, however we may balk at the terms." This writer was not afraid to call a spade a spade, and he states a psychological truth. Another writer in the same magazine, says: "Advertising is just salesmanship on paper; a mere money-

making means of selling goods rapidly. That 'mysterious something' is just printed persuasion and its other name is 'selling conviction.' Conviction may be imparted *at will* by those few writers who have closely studied the thought process by which conviction is induced. The mission of every ad. is to convert readers into buyers."

The main difference between business arguments and business Suggestion is that the former uses the Broadsword of Proof, and the latter the Rapier of Insinuation—the former appeals to the Reason, the latter to the Feeling and Emotions, and other subconscious mental faculties.

CHAPTER VII.

SUGGESTION AND CHARACTER.

By one's "Character," we mean one's "mental qualities or attributes." Reputation is the opinion that others entertain regarding one; Character is the sum of one's mental qualities and attributes, as they really exist. Character is held to be the result of heredity plus experience and environment. In environment and experience must be included Suggestion. Education is largely a matter of Suggestion; in fact, some leading authorities claim that a man's education is composed almost entirely of Suggestion of some kind. Without entering into a discussion of this question, it may be asserted with safety that a man is largely what he is by reason of the suggestions which he has *accepted.* Remember, we say "accepted," rather than "experienced"—for one experiences many suggestions which he rejects and refuses to accept. The rejected suggestions affect his character only in an indirect way,—

that is in the way of forming a habit of the rejection of similar suggestions. The suggestions which are *accepted* become a part of his nature and character, and may be removed only by suggestions of an entirely opposite nature, strong enough to neutralize the first ones. This being understood, it will be seen what an important part Suggestion plays in the part of all of us.

The suggestions which so forcibly impress themselves upon our characters may reach us along any of the various lines of Suggestion, as stated in the preceding chapters. The Suggestion of Authority is one of the first forms of Suggestion that makes its impress upon the youthful mind. The statements, views, opinions and actions of those to whom the child looks for authority are impressed strongly and deeply upon the child-mind. Acting along with this form is Suggestion of Imitation. The child is an imitative creature, and instinctively "picks up" the ideas, opinions and mannerisms, as well as the general code of life of his elders. The child naturally acquires the impressions suggested to him, involuntarily or voluntarily by those with

whom he associates. He grows to resemble those with whom he is surrounded. He is like a sponge absorbing ideas from his associates, particularly his elders, for his nature is to take in and absorb from the outside world. The mind in childhood is particularly plastic, and the habits of his after years are largely influenced by the impressions of his early youth. Certain wise churchmen are reported to have said: "Give us the first seven years of a child's life, and you may have the rest." And if those first years have been given to those whose suggestive influence is undesirable, that child will have hard work to eradicate the early impressions, in after years.

Halleck well says: "The analogy between the plasticity of nerve and brain and that of plaster of Paris has often been pointed out. The freshly mixed plaster can easily be moulded at will, as can a youthful brain and nerves. Persons after the age of thirty seldom radically change their habits; indeed the age of twenty finds most of our habits already outlined as they are to remain for life. The boor at that age will continue to have

boorish peculiarities. Errors in grammar will slip automatically from the tongue. The doctor, the lawyer, the clergyman, the business man, the teacher, soon acquire the peculiar habits of their professions. If we do not get into the right vocation early in life, we are caught in the vise of habits ill-adapted for a change. Our very ways of looking at things have become crystallized. If we put off learning new subjects, we shall remain ignorant of them." While we differ from Prof. Halleck, inasmuch as we claim that The New Psychology has pointed out methods whereby habits may be changed in after life, yet we agree fully with him in his statement regarding the strength of the impressions and suggestions accepted during youth.

But, the effect of Suggestion upon character does not cease with the passing of youth. We are affected by it during our entire life. We are constantly being built up from the Suggestions we accept. If we yield to the inspiring, hopeful, courageous suggestions contained in the words or examples of others, we tend to develop similar qualities in ourselves. If, on the contrary we allow the pessimistic,

discouraging, hopeless suggestions of failure, from the words and examples of others, to sink into our minds, we tend to grow in accordance therewith. Our thoughts, ideas, actions and habits become formed from the example and precepts of others, modified of course by our own thoughts on the subject. But even our thoughts and opinions are largely the result of the thoughts and opinions of others which we have *accepted.* Our lives are being modeled from the patterns which we accept from the outside world—therefore we should be very careful what patterns we accept.

It has been often well-said that we are the result of what we have thought. And it is likewise true that we have thought largely what we have accepted and selected from the suggestive influences around and about us. It takes a very strongindividual to rise above the effect of his environments, and to shake off the prevailing opinions of his associates and strike out in a new line for himself. Such men are akin to geniuses—the ordinary mortal finds himself incapable of effecting the task, unless he has been inspired to renewed and

scientific effort by the helpful suggestions and influence of others who know whereof they speak. Take a child of the very best heredity, and place it among the thieves of Whitechapel, where it has constantly set for it the authority and example of vice, and it will require almost a miracle to save it from falling into the pit of crime. The inhabitants of a neighborhood grow to resemble each other in many ways, owing to the force of mutual suggestion and example. Removal from one neighborhood to another—from one town to another—has changed the life of many persons, for better or for worse. These facts should not need further proof or argument—the use of one's powers of observation should be sufficient to render them self-evident.

The consideration of the above stated facts may tend to produce a feeling of sadness or discouragement in the minds of some who may read them alone, without reference to the remedy. And, indeed it surely would be a sad and hopeless state of affairs were there no remedy. But Nature always supplies an antidote for every bane—and those who seek the remedy will always find it. Nature has

given man a Will—a Will to use and order his life and character as he will. And by that Will he is able to *reject and refuse* the suggestions which are not conducive to his welfare —and to seek, welcome and accept those which are calculated to strengthen and build up his character along the desired lines. If man were but the creature of chance and circumstance, then indeed would he be but as an automaton moved by the wires of fate, circumstance and environment. But with the possession of the Sovereign Will, he may cast aside and away from him the injurious things, and draw to himself those calculated to help and develop him.

No one is compelled to *accept* a suggestion —no one is prevented from rejecting one. On the contrary every person has the power to choose and decide between the impressions coming to him from the outside world, and to accept or reject as he wills. By the proper mental attitude one may cause adverse suggestions to fly from him as the bullet is deflected from the steel armor of the battle-ship. And by turning the attention toward the kind of suggestions he wishes for,

he may discover them and select them as his own from amidst the mass of impressions of the contrary character. One draws his own to him—he finds that for which he seeks. As Kay says: "When one is engaged in seeking for a thing, if he keep the image of it clearly before the mind, he will be very likely to find it, and that too, probably where it would otherwise have escaped his notice. . . . Truly we may say of the mind, as has been said of the eye, that 'it perceives only what it brings with it the power of perceiving." And as John Burroughs has aptly illustrated: "No one ever found the walking fern who did not have the walking fern in his mind. A person whose eye is full of Indian relics, picks them up in every field he walks through. They are quickly recognized because the eye has been commissioned to find them." And the mind may be commissioned to find the things needed and sought for, as well as may be the eye.

Halleck well says, regarding the power of the will to shape one's thoughts, desires and actions, instead of allowing them to be controlled from the outside, along the lines of

Suggestion: "In the capacity for attention, we have the key to the freedom of the will. *Voluntary attention* makes the motive. The motive does not make the attention. Hence the motive is a product of the Will. If I withdraw my attention from a motive idea, it loses vigor, like a plant deprived of air and moisture. . . . By sheer force of will-power, many a one has withdrawn his attention from certain temptations, centered it elsewhere, and thus developed a counter motive." And here is where the individual may make use of the power of outward Suggestion in his own development of character. By refusing to allow his attention to be attracted or held by impressions and suggestions, (or their sources) which are detrimental to his welfare, he renders them ineffective and of no avail. Likewise, by holding his attention ever open for, and then firmly fixed upon those which are conducive to his welfare, he may surround himself with a continuous atmosphere of helpful and uplifting suggestive impressions, which will inspire and strengthen him. Man is the master of Suggestion, if he will but use the Will with which Nature has endowed him.

Under the subject of Auto-Suggestion, which will be considered in the latter part of this book, the reader will find taught a system of self-development, or Character-Building, which will be found not only to develop one along desired lines, but which will also tend to attract to himself suggestive influences in harmony with his own character—for like attracts like in the world of thought and Suggestion, as in every other field of Nature's operations.

CHAPTER VIII.

SUGGESTION IN CHILDHOOD.

In the preceding chapter we called your attention to the fact that the period of childhood is one in which mental impressions or suggestions are readily accepted, and firmly retained in the character. This fact is lost sight of by the majority of parents and teachers, who seem to think (if they think of it at all) that the child's mind works precisely like that of the adult. They imagine that a child should be able to *see* and understand the reason of things, and to be amenable to appeals to reason, whereas the child has not fully reached the reasoning stage, as the term is generally used. The child is governed almost altogether by the feelings and emotions, and from the effect of impressions and suggestions received from those around it. This being the case, we may see how careful we should be to avoid the use of improper suggestions to the child; and to use the proper ones. The child naturally accepts the suggestions of its

parents, in a way that would surprise the parent could he or she but get a glimpse of the workings of the little mind.

Too often is the child impressed with the idea that "Johnny is such a stubborn child—he cannot be moved when he makes up his mind to a thing." Or, "Edward Everett is *so delicate;* the least thing upsets him. We have to be *so* careful about him." Or "Mary has the *meanest* disposition—she seems to do things just to spite one, and annoy those around her." Or "Samantha is too stupid for anything; she acts as if she wasn't just right in her senses, sometimes." And so on, *all in the presence of the child!* And the amazing thing is that the parent, or teacher, does not seem to realize that the child listens attentively to what is said, and grows to accept the Suggestion of Authority and Repetition, and naturally acts along the lines of the suggestion. Thought takes form in action, and these mental images manifest themselves in material form. The child feels that he is just what his elders are claiming for him, and naturally falls into line. Long before the parents realize it, the child is forming habits of

character from these repeated suggestions made about it in its presence. The process is simple—the child does not *reason* over the matter and then decide to act upon the suggested characteristics. Its subconscious mentality, or habit-mind, simply absorbs these suggested impressions, and when they are repeated many times a day the impression becomes fixed in that region of the mind. Just imagine yourself (*you* who are reading these words) being subjected to a running fire of verbal criticism of this kind. Would you not tend to "make good" the bad qualities attributed to you? Would you not, eventually, grow to play the part assigned to you? That is, if you didn't rebel and change your environment. The child cannot change its environment, but must stay where it is and listen to this perpetual flow of adverse suggestion, week in and week out. And, when you realize that the child's mind is a hundred times more impressionable than is your own, you may begin to understand the effect of these suggestions upon it.

In the same way the repeated remarks of some foolish mothers, that "Eloise is such a

beautiful child; people notice her on the streets, and turn around to watch her,"—*this in the presence of the child*—must exert an influence over the mind and future character of that child. And the common suggestion that "Carmencita is *so* bashful; she is always afraid of strangers, and I cannot get her to 'make up' to them"—now, just imagine what that must mean to the sensitive child when she hears it said in her very presence and that of the stranger! How would you feel, if you were sensitive, and your friends should say in your presence when you met a stranger for the first time: "Oh Mr. Brown, you must really excuse Miss Psyche's bashfulness—she is so shy and retiring—she blushes every time she meets a stranger, and cannot think of a word to say!" How would you relish having salt thus rubbed in the open wound of your self-consciousness? Multiply your feelings by ten, and you have the child in question. Cannot you see that you are using the very strongest possible method of developing the self-consciousness of the child—the very means that you would use were you actually *trying to make* the child shy and bashful. Be-

sides the shock to the sensitive nature, you are also actually building character in the child along the lines of the Suggestion of Repetition.

We have seen mothers cry out to children who had picked up an ornament: "Oh, Mabel, you'll *drop* it—look out *it will slip from your fingers*—take it away from her, *quick*, before she *drops* it!"—and more of the same kind. When one realizes that it is by precisely this class of suggestions that suggestible subjects are made to perform actions in experimental psychology, one may wonder why Mabel does not drop the thing at the first suggestion, not to speak of its insistent repetition—and often she does. A kindly, "Put it back in its place, Mabel; mother doesn't like her vases moved about," would be better calculated to preserve the integrity of the vase. Similar to this is the suggestion of: "Oh dear, she'll fall down the stairs—look out dear, *you'll fall;* you'll fall in a minute; look out now!" Can you wonder if the child does fall, after a suggestion like that? Can't you see that you are supplying motive power for the suggested action. In such case, the thing to do is to keep

cool, and above everything else not to let the child catch your fearthought. Fear is contagious, by the channel of Suggestion. If you have ever witnessed any experimental work in psychology, in its branch of Suggestion, you may begin to appreciate the motive force latent in a strong Suggestion to an impressionable mind—and children have impressionable minds.

We feel annoyed that we should have to include any reference to the criminal practice of giving children the suggestion of Fright—this subjects belongs to the Dark Ages of child-rearing, but alas! we hear of new instances of its persistence, every few days. When one thinks of the terrors of the little mind due to the suggestions poured into it regarding "Boogy-men"; "Shadow-men"; "Big Bear will Catch You!" "Something will grab your foot if you step out of bed!"; "Better look out when you go up the dark stairs!"; and all the rest of the infernal suggestions of that kind, one feels it difficult to speak with the conventional restraint. We have known women of middle-age who have never been able to outlive these fear-impressions given in early

youth. The "Big Bear" is so firmly lodged in their subconscious mind that all their knowledge and reason is not sufficient to eradicate it. As the well-known Englishman, of undoubted bravery and highest reasoning faculties once said: "I laugh at and believe nothing of the grisly things in the daytime; but in the midnight darkness of my bed-chamber I find myself believing in all the horrors of my childish imaginings." And all this the result of these criminal suggestions. Many a child has been rendered "nervous" and "fearful" for the rest of its life, by these "Boogy-boos" of childhood. To one who understands the workings of the Law of Suggestion, such things seem as bad as witchcraft and sorcery.

The reverse of this general proposition is true. Just as adverse suggestions may be harmful to the child, so may the proper ones be helpful. If you must make suggestions to, and about the little one, use as their subjects the favorable points of the child, or those in which you wish the child to improve. In the case of the bashful child, give it the silent Suggestion of Association by ignoring its shyness,

—take no notice of its failing, and see that your friends act likewise. Soon the child, seeing that it is not noticed at all, will begin to evince the natural childish desire to attract attention, and will begin to come out of its shell. The child with the dirty hands may be put on its mettle, by calling the attention of friends to how Johnny is getting to be a big boy now, and how much cleaner he is keeping his hands than when he was a little fellow. Always map your suggestions on *what you want the children to be,* not what you *fear* they will be, or are. Just as in Auto-Suggestion, you hold the mental image of *what you wish to become,* as a pattern upon which your subconsciousness will model your new character—so should you ever hold before the child a mental picture of that which you wish it to be. Do not misunderstand us—we do not mean to advise *preaching* to the child, no child likes that—we mean to act, and suggest, that the child actually *is* becoming or acting as you wish. You will get the idea better if you will *reverse* the line of suggestions objected to by us in the first part of this chapter. Encourage the positives—and the negatives will die

away. Cultivate the desirable tendencies, and the undesirable ones will die for want of nourishment.

Above all, realize that the mind of the tiny child is like a soft impression plate, or a sensitive photographic film—therefore be careful what objects of suggestion you place before it. Place bright, strong, positive pictures in its mind, and avoid those of the opposite kind.

In conclusion, we would remind you that the actions, views, ideas, and general life of the parents act as suggestions for the child. "Like Papa and Mama," is the instinctive idea in the mind of every child, from its earliest days. Therefore "Papa and Mama" have considerable responsibility in this direction, during the early days of the child particularly. What Papa or Mama do, is Gospel to the child—everything, good and bad, is worthy of imitation. Suggestion of Imitation is always active in the family. Govern yourselves accordingly. Teachers have the same responsibility—"Teacher does it," is a sufficient excuse for the child. There is always a case of "a chiel' among us, takin' notes."

And these notes are suggestive notes. We feel that a whole book might well be written on this subject, in order to do it even faint justice. But we trust that the hints that we have given here may reach some for whom they are intended, and who need them very much. You may not be able to give your children the riches or "advantages" that you would like to bestow upon them (perhaps that is so much the better for them) but you have the opportunity of giving them the best possible Suggestions—the "best in the shop," and that is *much,* very much indeed.

PART II

THERAPEUTIC SUGGESTION

CHAPTER IX.

SUGGESTION AND HEALTH.

Perhaps in no other way is Suggestion so commonly accepted by people as in relation to their physical condition, or health. People are being made sick, and others are being made well, every day by Suggestion pure and simple. We purpose devoting a number of the chapters of this book to various phases of Suggestive Therapeutics, but it may be as well, at this point, to call your attention to the undoubted effect of Suggestion upon the physiological functions. Science has recognized this fact, and modern medicine takes it into serious consideration. Cults and schools of thought have been built upon this fact, and the underlying principle has been lost sight of by the various theories, explanations, dogmas and ideas philosophical and theological which have gathered around it. Some of the authorities call it "The Effect of the Imagination upon Physical States," or "The Power of Mind over Body"—but Suggestion is the

active principle of application in all the various forms, and under all the various names, and in spite of the conflicting theories.

That mental states affect physiological function is admitted by the best authorities in medical science, and has been for many years. But it is only of later years that methods of applying the principle have been taught and practiced to any great extent. Previous to that time the principle was mentioned only in connection with the production or induction of disease by adverse mental states. Perhaps a consideration of the older authorities might be interesting and instructive, at this stage, and before we undertake the general subject of Suggestive Therapeutics.

Sir Samuel Baker, in the *British and Foreign Medico-Chirurgical Review,* said: "Any severe grief or anger is almost certain to be succeeded by fever, in certain parts of Africa." Sir B. W. Richardson, said: "Diabetes from sudden mental shock is a true, pure type of a physical malady of mental origin." Sir George Paget, said: "In many cases I have seen reasons for believing that cancer has had its origin in prolonged anx-

iety." Dr. Murchison said: "I have been surprised how often patients with primary cancer of the liver have traced the cause of this ill-health to protracted grief or anxiety. The cases have been far too numerous to be accounted for as mere coincidences." Prof. Elmer Gates, says: "My experiments show that irascible, malevolent and depressing emotions generate in the system injurious compounds, some of which are extremely poisonous; also that agreeable, happy emotions generate chemical compounds of nutritious value, which stimulate the cells to manufacture energy." Dr. F. W. Southworth says: "If mental causes can change the various secretions of the body, making them poisonous, for example, the saliva, and the milk in the human breast, under the influence of anger, worry or fear, could it not also be productive of disease through imperfect or non-elimination? Is it improbable that fear, which is a greater negative force than anger, may produce the results as indicated?" All of the mental states above-mentioned as affording a probable cause of disease can be and are produced by Suggestion or Auto-Sugges-

tion. While that mysterious force behind the mental states may escape our definition, unless we consider it to be some phase of the Will, nevertheless we may safely assert that in Suggestion we find the motive power which calls this force into operation.

In the same way, that which people call "Imagination," is seen to be but a mental picture created in the imaginative regions of the mind by Suggestion, and afterward materialized by Fear or Faith, both of which act in the same general manner. The following interesting quotation from Prof. Halleck will show the effect of these suggested mental images, considered as products of the Imagination: "When a mental image is taken for a reality, the most astonishing results often follow; indeed, sometimes they are more pronounced than if the image were a reality. One may find many illustrations of this in every-day life. . . . Were it not for this power of the imagination, the majority of quack nostrums would disappear. In most cases bread pills, properly labeled, with positive assurances of certain cure accompanying them, would answer the purpose far better

than these nostrums, or even much better than a great deal of the medicine administered by regular physicians. . . . There is perhaps not a person living who would not at times be benefited by a bread pill, administered by some one in whom great confidence was reposed. . . . Warts have been charmed away by medicines which could have had only a mental effect. Dr. Tuke gives many cases of patients cured of rheumatism by rubbing them with a certain substance declared to possess magic power. The material in some cases was metal; in others wood; in still others, wax. He also recites the case of a very intelligent officer who had vainly taken powerful remedies to cure cramp in the stomach. Then he was told that on the next attack he would be put under a medicine which was generally believed to be most effective, but which was rarely used. When the cramps came on again, a powder containing four grains of ground biscuit was administered every seven minutes, while the greatest anxiety was expressed (within the hearing of the party) lest too much should be given. Half-drachm doses of bismuth had never pro-

cured the same relief in less than three hours. For four successive times did the same kind of attack recur, and four times was it met by the same remedy, and with like success. A house surgeon in a French hospital experimented with one hundred patients, giving them sugared water. Then, with a great show of fear, he pretended that he had made a mistake and given them an emetic instead of the proper medicine. Dr. Tuke, says of this case: 'The result may easily be anticipated by those who can estimate the influence of the imagination. No fewer than eighty—four-fifths—were unmistakably sick.' "

You are familiar with the old cases of people who have been told repeatedly that they were looking very sick, as a practical joke, and who took to their beds with various ailments. Also of the man who thought he was bleeding to death, from hearing the dripping of water accompanying a slight incision made in his arm by surgeons—actual death ensuing from the shock and fright. Many similar cases are related in the annals of medicine. Every professor in a medical college has had numerous experiences in which stu-

dents took on the symptoms of the various diseases which they had been studying. It has been estimated that as many die from fright during great epidemics, as from the disease itself. We have had the personal assurance of a reputable practitioner of medicine, that he once attended a case in which the patient believed that she had taken a dose of strychnine by mistake. When the physician arrived the patient was showing all the symptoms of poisoning from strychnine (she had previously witnessed the death of a dog from a similar poison) and only recovered after the usual antidotes and treatments had been administered—as it was she was weak for a long time afterward, notwithstanding the fact that after the doctor had left, the bottle of poison was found untouched, the woman having taken some harmless mixture. Many physicians of long practice relate similar experiences in their own professional life. Fright is a virulent poison, in many cases—just as joy is a powerful restorative and invigorant.

Dr. Geo. R. Patton in a paper read before a medical society in 1900, made the following

statements: "The mind as a dynamic force exerted over the functions of the body has been, doubtless, operatively manifest from the cradle of our existence. Though the fact may not have been so recognized at this primitive period, it is really the explanation of the cures which were then attributed to the influence of the stars, to divinations, talismans, charms, *et id omne genus;* for in the infancy of our race there were neither doctors nor drugs, the means of cure being wholly mental, aided by the so-called 'efforts of nature.' Herodotus tells us that the Babylonians, Chaldeans, and other nations of antiquity had no other physicians and used no medicines. Even when the practice of healing passed from the East into Egypt, and thence into Greece, it was exclusively confined to the temples. At this period it was the universal belief that all diseases were due to the anger of the gods, and, therefore, prayers, with ceremonies of pomp and mysticism were used to propitiate heaven in favor of the sick, and all were of such a nature as to act vividly upon the imagination and emotions. . . . Now these measures, in their entirety, were well calcu-

lated to arouse a new and favoring action in the nervous centres, and through them a sanative influence over the assimilative and nutritive processes, as well as upon the organic functions. At a later period, when medicine first began to be disseminated from Greece into the outer world . . . if recovery took place it was accredited wholly to a charm, incantation, amulet or talisman, which had now, in part, taken the place of the ceremonies in the temple, as the means of cure. Here, again, we see the effects of credulity and superstition exercised through the emotions and imagination upon the ills of the body. At still a later period in the history of medicine, magic and medicine were almost synonymous terms; in fact, the practice of medicine consisted almost wholly of the machinery of magic. A word scrawled upon parchment, for instance, would cure fevers; a hexameter from the Iliad of Homer cured gout, while rheumatism succumbed to a verse from Lamentations. These could be multiplied, and undoubtedly all were equally potent of cure in like manner. The repulsive and ridiculous agents at one time so often and so freely given

to the sick could only have been curative through a mental impression transmitted to the body; for who could take a potion from the skull of a murderer; or a tincture made from the common louse; or a pill from the dried liver of a bat; or a powder from the heads and legs of spiders, without profound emotion? Even now, new, unusual and untried remedies are often more efficient than the old and well-tried ones, and the shrewd and knowing doctor often avails himself of this fact."

In each and every one of the instances mentioned above the effect was undoubtedly caused by the power of Suggestion, in one or more of its various forms and phases. We shall continue this subject in the next chapter.

CHAPTER X.

MASKED SUGGESTION.

Not only in the ancient days was Suggestion, under various disguises employed to arouse the minds of the people in such a manner that therapeutic benefits were secured, but even in comparatively recent history—yes, even down to the present times, have the same general methods been employed with the same results. History constantly repeats itself, in Suggestive Therapeutics as in everything else.

All through the history of the race for the past thousand years, we find numerous instances of the employment of "Masked Suggestion"—that is Suggestion wearing the veil of some outward form or belief—operating to cure people of disease. We hear countless instances of holy wells, sacred grottoes, sacred relics, shrines, and other places associated with various religions, to which have been attributed wonderful cures of physical ailments. Many supposedly incurable cases have been

healed at these places, or by these holy objects. The shrines, and wells, and chapels are filled with the crutches of cured cripples, and countless well attested cases of marvelous cures are reported as having occurred. But similar cures have been recorded throughout all history, accompanying all forms of religions, so that the scientific investigator soon comes to the conclusion that the only virtue in the religious association of the cure consists in the faith and association in the mind of the patient, along the lines of Suggestion. The same results are obtained by so many different methods, and under so many different phases of religious belief, both Christian and "pagan," that it must be conceded that the real cause lies far back of creed, form, or ceremonial. And Suggestion is seen to be the real cause. There is a well-known case related of a "Sacred Bone" which obtained great repute in the Middle-Ages from its wonderful power to heal diseases. This bone had been brought from the Holy Land by two soldiers of the crusades, and was supposed to be a portion of the skeleton of some great character of the New Testament. It was only upon the death

of one of these soldiers, years after, that the truth became known. On his death-bed the soldier confessed that he and his companion becoming drunk on the journey, had lost the real relic which they were transporting from the Holy Land. Fearing to return home without it, they substituted the bone of a sheep which they found in a field. Much to their surprise this sheep-bone operated as the means of wonderful cures, and they agreed to keep the matter silent. In this case, as in many other of a similar nature, the faith and belief of the people, acting along the lines of Suggestion, operated as a dynamic power for producing physiological changes and operations, which resulted in the restoration of health to many a suffering mortal. After the disclosure of the nature of the relic, the cures ceased at once, and many of those who had been healed became sick again.

The kings of England and France were formerly believed to possess great healing powers, applied by laying on the hands. This was known as the "Royal Touch" and was believed to be specially efficacious in cases of scrofula. Thousands were cured of this and

similar diseases, and the gift was never doubted. Wiseman, a noted surgeon of several centuries past, has written of the Royal Touch: "I myself have been an eye-witness of many thousands of cures performed by his majesty's touch alone, without the assistance of medicine or surgery, and those, many of them, such as had tired out the endeavors of able surgeons before they came hither. I must needs profess that what I write will little more than show the weakness of our ability when compared with his majesty's, who cureth more in one year than all the surgeons of London have done in an age." The virtue of the Royal Touch was not doubted, until in the seventeenth century when there arose a pretender by the name of Greatrakes, who claimed to possess the Royal Touch, and who healed thousands of people by laying on of hands. So marked was his influence that the throne became worried, for the people were muttering that Greatrakes must be the descendant of a former king, and rightful heir to the throne. The Royal Chirurgical Society of London investigated Greatrakes and his cures, and made a report stating that his cures

arose from "some mysterious sanative contagion in his body." Modern students of Suggestion give a more scientific explanation.

Similar to these cases is that of Elijah Perkins, a Connecticut blacksmith, who invented a set of "metallic tractors," which were a tong-shaped contrivance composed of several kinds of metal. These tractors were applied to the affected portions of the body, and wonderful cures were reported as the result. A great furor arose from the character and number of cures thus made by Perkins, and he founded a school of the healing art which was called "Perkinism." New England was set ablaze by the new wonder, and the contagion rapidly spread over the rest of the country. Thence it was carried to England and the Continent, with equal success. Schools and hospitals were erected, in which "Perkinism" was practiced. The records of the time state that over a million cures were made in Europe alone. People high and low, were treated with more or less success. The bubble was finally punctured by Dr. Haygarth of London, who held that the cures resulted from the imagination rather than from any

virtue inherent in the tractors. Accordingly he proceeded to prove this theory, in the following manner, as reported by a chronicler of the time: "He formed pieces of wood into the shape of tractors, and with much assumed pomp and ceremony applied them to a number of sick persons who had been previously prepared to expect something extraordinary. The effects were found to be astonishing. Obstinate pains in the limbs were suddenly cured; joints that had long been immovable were restored to motion, and, in short, except the renewal of lost parts or the change in mechanical structure, nothing seemed beyond their power to accomplish." These results, when explained, punctured the bubble of "Perkinism," and the craze subsided. In this case, as in the other the "imagination" was simply a form of Suggestion along the lines of which we have spoken in preceding chapters.

The success of Dowieism, and similar religious or semi-religious cults all go to prove the same thing—the existence of some fundamental principle underlying all of these opposing claims, which operates whenever and

however it may be invoked. Dowie undoubtedly cured thousands of people in spite of the crudeness of his methods and creed, and in spite of the ridiculous nature of his claims. And so it is and has been, and will be with other similar cults. They make about the same percentage of cures, because they apply the same fundamental principle of Suggestion masked by their various creeds, beliefs and forms of application. The Emmanuel Movement which is attracting so much attention at this time, employs the same fundamental principle, but unlike its predecessors it frankly acknowledges the nature of that principle, and admits that it is Suggestion. The religious atmosphere and influence surrounding these "church-cures" is especially adapted to arousing the feelings of faith, belief and religious emotion in the patient, and these are among the strongest emotive factors in mental cures, as they serve to bring into operation the dynamic force of the mind of the patient, which tends to restore normal functioning. In fact, we freely admit that many of these cures would not have been accomplished by the methods of the ordinary practitioner of Sug-

gestion, for the reason that the latter would not have been able to arouse the emotional power of the patient sufficiently. The greater amount of emotive power and expectant attention that the healer is able to arouse in the patient, the better are the chances of a cure.

Physicians know the value of the "placebo," which is simply a harmless prescription, consisting either of flavored water, or a pill of no medicinal effect, or similar thing. It is the idea of the celebrated "bread-pill." Every physician knows of many marvelous cures effected by these harmless "medicines," the effect depending altogether upon what the physicians formerly called "imagination," but which they now know as Suggestion. Sir Humphrey Davy once cured a difficult case, by the virtue of the clinical thermometer, which the patient declared made him feel much better the moment it was applied to his mouth. Many patent-medicine cures have been made in the same way. The various decoctions formerly sold by the street-corner fakirs in the country towns, cured people in the same way. The thousand-and-one appliances and contrivances so extensively adver-

tised in the rural newspapers, depend upon Suggestion for their curative virtue. They all make cures—and in the same way.

Now all this does not mean simply that these "imaginary" cures are unreal, or cures of imaginary diseases, as so many have assumed. It simply means that they act in the direction of arousing the dynamic latent forces of the mind, along the lines of Suggestion. And these mental forces are sufficiently powerful to act and react upon the bodily functions and organs. None of us need to be told of the fact that mental states have a direct effect upon physical functions. Who does not know the effect of fear, grief, or joy on the functions of digestion, assimilation and elimination? The change of a mental state reacts upon the physical system at once. We lose appetite upon the receipt of bad news; but good news makes us feel like enjoying the meal. A disgusting sight, or recollection will produce nausea. The thought of certain food will cause the saliva to flow, and the gastric juices to be secreted. There is no nonsense, or fanciful imagination about these things—they are psycho-physiological facts,

known and taught in text-books upon the subject.

And sane, rational, scientific Suggestive Therapeutics is based upon this fundamental principle of action and re-action between mind and body, or rather between the brain-mind and the mind in the cells and organs of the body, for it is now known that there is mind in every cell and centre of the physical body. In the chapters following the present one, we shall call your attention to both the theory and practice of Suggestive Therapeutics, as taught by the best authorities of to-day. It is a subject well worth the careful attention and study of every thinking person.

CHAPTER XI.

SUGGESTIVE THERAPEUTICS.

The term, "Suggestive Therapeutics" has sprung into popular use during the past ten years, by reason of the fact that Suggestion has come to be recognized in regular medical circles as a valuable method of treating many forms of mental and physical disorders. While the term is often used in its narrow significance of treatment by Suggestion as Suggestion, with the full knowledge on the part of the patient of the underlying principle, still it is properly applicable in all cases of healing or treatment of disease in which the mental activities are brought to bear on the body, by means of masked suggestions, advice, or "statements" of the various schools of metaphysical healing, including the religious or quasi-religious sects and cults. In this broad sense, Suggestive Therapeutics today must be recognized as one of the most popular and commonly used methods of treatment of physical disorders. And, brushing aside the

fanatical claims and theories of some of the cults, there will be found a solid foundation of fact underlying the various methods employed.

Suggestive Therapeutics as a science is emerging from the mists and clouds of superstition and fanatical statements and beliefs, and is asserting its right to be considered as any other science—on its merits, and with a fair and open mind. This is being recognized by many of the leading minds in and out of the medical profession, although many of the ultra-conservatives still linger in the rear, protesting against the innovation. But constant progress is being made. As Max Eastman says in a recent magazine article: "The mission of this paper is to offer guidance in a matter about which a great quantity of the general public is very much at sea. In this question of 'mind over matter,' the reformers have done their work. They have stirred things up. They have bestowed upon the world about a hundred and fifty little religions and a confused idea that there must be some truth in the matter somewhere. The ignorant have done their work. They have perse-

cuted the believers, jeered at them, or damned them with a vacuous smile. This world will never lack ballast. It is only the scientists that have failed of their duty. They have stalked through a routine of elevated lectures, written a few incomprehensible books, and kept the science of Psychology, so far as the hungry world goes, sealed up in their own proud bosoms. In all this uproar of faith-cures, and miracles, and shouting prophets, we have heard few illuminating words from the universities. The consequence is that we are without a helm, and the reform blows now one way and now another."

The rapid rise of what is known as "The Emmanuel Movement" has served to bring a great number of conservative people to realize that many cures may be made by Suggestive Therapeutics, pure and simple, under the auspices of church organizations, but without the accessories of fanciful metaphysical beliefs or theories. The fact that these Emmanuel healers are accomplishing the same results, without making the claims of metaphysical schools on the one hand, or the claims of a monopoly of the healing power on the other, has opened

the eyes of many people who heretofore have thought that the healing power of the cults was due to some special power not connected with the ordinary natural principles recognized by science. The Emmanuel Movement is yet in its infancy, and there is room for great improvement in some of its methods, but the honesty of its teachers and healers cannot be questioned, and there has been manifested a steadfast determination to avoid claiming any miraculous powers or monopoly of truth. The rise and popularity of this movement is a hopeful sign, and one that encourages those outside of the movement who have long been interested in the subject of Suggestive Therapeutics.

At the same time there is to be found, both in this country and abroad, a rapidly growing body of earnest workers among the ranks of the medical profession, who use Suggestion in their practice, with excellent results. These men have found that many disorders which were formerly considered as having purely physical causes, really have their roots and causes in mental states and conditions. Consequently they treat the source of the trouble,

instead of the symptoms, with excellent results. And, these men have also found that even in cases of purely physical troubles, the mind may be directed toward strengthening and stimulating the various organs to normal functioning, by means of Suggestion. And it is here that the great field for future investigation and experiment opens out to these earnest seekers after truth in their profession. The day for antagonism between the "Mind-Cure" people outside of the medical profession, and the practitioners of "Suggestive Therapeutics" within the profession, has past. The era of mutual understanding and co-operation has arrived. We are speaking now of the people, on both sides, who have truth and results as their sole object and aim —but where personal gain is allowed to interfere, there must always be jealousies and friction.

In order to give you a fair idea of the general opinion of the medical practitioners of "Suggestive Therapeutics," we ask that you read the following quotation from Max Eastman's magazine article, before referred to. Dr. Eastman says: "The Law of Suggestion,

which is one of the great discoveries of modern science, was first formulated by Dr. Liebault at Paris, in a book published in 1866. Since his day the number of physicians who practice 'suggestive therapeutics' has steadily increased, until to-day no thorough clinical hospital is without a professional suggestionist. The practice does not involve any metaphysical theories, the passage of any hidden force from one brain to another, any 'planes of existence,' or any religious upset, or any poetic physiology, or the swallowing of any occult doctrines whatever. It is one of the simplest and coolest of scientific theories. It is a question of the relation between the brain and the bodily organs. It seems never to have been clearly stated that healing disease by suggestion depends not in the least degree upon any theory of the relation of mind and matter. . . . The attempt to fix an idea in the mind without reason is suggestion. It is accomplished usually in medical practice by asking the patient to lie down and relax his body and his mind and then vigorously stating to him the desired idea. It may be accomplished in a number of ways. The patient

may be told that the operator is a wizard and is about to transfer an idea from his own mind to that of the patient. If the patient believes him he will very likely accept the idea. It may be accomplished by gestures or incantations which the patient regards with superstitious awe, provided it is explained beforehand what these gestures are meant to produce. It may be accomplished by telling the patient he has no body, and sitting with him for a while in spiritual silence, provided he knows what to expect. All these methods, if one believes in them, are good, and they prove by their success the law of suggestion. But the method that is based on a sure truth is the method of the scientist. He reasons with his patient, he stirs in him what moral and religious enthusiasm he can, and to these means he adds tactfully the subtle suggestive powers of his own presence and eloquence. This force, together with the power which is revealed in a man of correcting his own mental habits, is the greatest practical discovery of modern psychology. . . . Suggestive therapeutics is the use of suggestion to fix in the mind ideas of health, or healthy mental habits."

Dr. Eastman has well expressed the scientific view of Suggestive Therapeutics in the above quotation. He calls attention to the fact that while scientific suggestionists recognize the fact that in a number of persons the fanciful appeals to superstition, credulity, and fantastic theories will yield beneficial results, still the tendency and desire is toward educating the patient up to an intelligent understanding of the nature of the principle of cure, and the actual operations thereof. This, of course, should be the aim of every true suggestionist, although personally we can understand the position of some practitioners whose patients are largely recruited from among the ignorant classes, and who would simply mystify and bewilder their patients were they to attempt to explain the scientific principles of Suggestion. These practitioners may be excused when they claim that "the end justifies the means," and in their position that in the case of the very ignorant patient the best way is to *cure him first,* and then to explain so far as is possible, afterward. In this spirit there are many physicians who, recognizing a case for Suggestive treatment in a patient of

this class, consider that the best way to administer that suggestion is by means of colored, flavored and sweetened water, or other *placebo,* accompanied by strong, positive repeated suggestions of *what the medicine will do for the patient.* A *placebo* administered in this way, a half-teaspoonful to be taken every half-hour, becomes a most powerful suggestion. In the first place, there is the strong Suggestion of Authority of the physician, and the Suggestion of Repetition which is caused by the frequent taking of the dose, each dose being a reminder of the original Suggestion. Many cases reached in this way, could not be reached by ordinary Suggestion, with a scientific explanation—the patient wouldn't understand it at all. In the same way a little trip, or a visit to some celebrated springs or health resort, acts as a strong suggestion, as all physicians know. These things all have their place, and have their uses and excuses; but the practitioner does not complete his work unless he finally dismisses the patient with a number of good suggestions, and a stock of good advice regarding personal habits, etc., which will tend to prevent a recurrence of the complaint.

No work, or chapters, on Suggestive Therapeutics would be complete without a consideration of the causes of the physical complaints amenable to the suggestive treatment. Therefore in the succeeding chapter we shall consider the same. In this part of the work we shall draw upon the knowledge and experience of some able practitioners, in and out of the medical profession, with whom we have been associated in experimental psychological work, in addition to actual cases which have come under our own personal experience. We shall avoid technical terms so far as is possible, as this book is in no sense of the term to be considered a "medical work."

CHAPTER XII.

MENTAL CAUSE AND CURE.

In order to understand the principles underlying Suggestive Therapeutics, we must consider the physiological causes of disease, or at least the first manifest physiological stage of disease. The best authorities now hold that disease is caused primarily by the failure of the cells to do their duty, or to repair their waste. Of course, it may be urged that there are mental causes behind this manifestation which operate in the direction of interfering with the activities or vigor of the cells. This we are prepared to admit, but even so it must be granted that in the above failure to function properly the cells manifest the first physiological stage of disease. This trouble may arise from the inefficiency or rebellion of a single cell, which then spreads its contagion to those around it, or else to a rebellion on the part of a group of cells. Or from a failure of various groups of cells to coordinate and co-operate. There are certain

actions among cell-groups which so closely resemble a mutiny, or rebellion, that it is impossible to avoid using the figurative term in describing them.

Each individual cell is a tiny life, having its various functions and activities—its mental as well as its physical side. Cells show varying degrees of what may well be called "intelligence." They have their memories, and profit by experience. They co-operate with other cells and often seemingly have civil war among themselves. Any failure on the part of the cells, or cell-groups to do their work, results in the symptoms which we call "disease." According to the size and location of the cell-disturbance does the disease become local or general. The disease is cured, either when the rebellious cells are forced to resume normal functioning, or else when they have been discarded and destroyed and replaced by new healthy normal cells which perform the tasks which their predecessors have abandoned. Therefore, any method or means which operates in the direction of restoring normal function to the cells, in the direction of stimulating, regulating, or removing obsta-

cles, tends to produce what it called a cure. And to this end Nature is constantly directing her efforts. And Nature is helped by the proper mental attitudes, or retarded by improper ones. Faith and confident expectation are wonderful aids to Nature in this work, while Fear and Apprehension are obstacles and detriments.

Recent discoveries have confirmed the views of the thinkers of a few years back who identified the mind in the cells, with a portion of that wonderful region of the mind called the subconscious. Each cell has mind in it, and belonging to it, but the various "minds" of the cells have mental filaments connecting with each other, and all connecting with the entire subconscious region of the mind. Therefore anything affecting the subconscious mind must of necessity affect the cells themselves, in varying degrees. Through the subconscious mind, and the sympathetic nervous system, are worked many important physiological changes. The concentration of attention upon any part of the body is known to affect the circulation of that part, and every student of Suggestive Therapeutics is aware that the

concentration of the patients thought upon any organ coupled with the idea of that organ being diseased is very apt to be followed by symptoms of imperfect functioning in the organ in question. Likewise the concentration of the attention upon an organ or part, with the idea that the organ has been invigorated and stimulated to proper and normal functioning, is very apt to be followed by results in accordance with the idea. To endeavor to explain "just why" this is so, would take us into the realm of theory, in which our own views would probably conflict with those of other thinkers upon the subject. More important than any theories are the known facts in the case—the facts stated above.

Physiologists interested in Suggestive Therapeutics endeavor to take the subject away from the region of Mental Science, and seek of find the explanation in the direction of the circulation by the attention, thereby building up the affected parts. Some speak, also of the increased flow of nervous energy to the affected part, by reason of the concentrated attention, and the expectancy. Along these lines, Dr. Eastman says: "Our question is:

Can those physical conditions of the brain affect the physical condition of the stomach? We know that the brain-condition which accompanies the idea of the raising our hand can affect the condition of the muscles of our arm—and we call that a voluntary function. Now the question is whether the brain condition which accompanies the idea of enlivening our stomach can have any effect upon that involuntary function. Experiments with suggestion have proved that in some cases it can, if it continues long enough. Persons of a very suggestible nature, can, for instance, by concentrating their mind upon a certain part of the body, increase the flow of blood to that part, although the regulation of blood flow is supposed to be entirely involuntary. The action of the heart, also the movements of the digestive organs particularly, and of the organs of elimination, are almost directly affected in suggestible persons by that change in their brains which accompanies certain ideas. . . . Science has established, then, that suggestion can effect to some extent, the so-called involuntary functions of the body; but the extent or limitation of these effects is by

no means determined. It could not be determined scientifically without years of diligent experiment and tabulation. Any dogmatic statement upon one side or the other of that question is therefore premature and against the spirit of science."

Along these same general lines, many writers on Suggestive Therapeutics have proceeded from the fundamental position that the healing effects result from the increased circulation and nerve-currents, directed to the affected parts by the unconscious volition of the patient which is aroused and directed by means of the suggestions given him. In this way the weakened digestive apparatus receives an additional amount of nervous force, and an increased circulation, both of which, as all physiologists admit, will tend to stimulate and invigorate the particular part, and be conducive to a resumption of normal functioning. That the circulation may be so directed is unquestioned. It is an axiom of Suggestive Therapeutics that: "The Circulation follows the Attention," and increased circulation means increased nourishment and building material. If the increased circulation be ac-

companied by increased stimulation by nerve currents, then it must be seen that an improved condition of the part or organ must result. Whether we accept this explanation as the last word in Suggestive Therapeutics, or whether we regard it as merely the statement of effects resulting from higher causes, we must admit that the circulation may be directed by the attention, and that stimulation must result from the increased circulation. The experiments of the psychological laboratories have shown us conclusively that the circulation may be increased in a hand or foot by simple suggestion. Personally, we have conducted experiments in which by suggestion the blood was increased in one hand and decreased in the other, at the same time—one hand assuming a dark red color, while the other appeared pallid. This result, of course, arose from the unconscious volition of the patient, directed by the suggestions given and accepted by him. Results far more startling are common to all experimenters along these lines. This being so, we can see the strength of the argument of those who claim that by this increased circulation in the affected part,

accompanied by an increased stimulation by nerve currents directed in the same way, and at the same time, the cures of Suggestive Therapeutics may be explained.

Personally, we think that the above theory or explanation is merely a half-truth. While freely admitting that increased circulation and nerve force is present in the cure, we think that there is still more to the process. Realizing the presence of mind in every cell, cell-group, and part of the body, we think that these "cell-minds" are acted upon by the central mind, just as the subconscious central mind is acted upon by the suggestions from outside. In other words, we believe that the central mind *superimposes* upon the "cell-minds" the suggestions given and accepted by it and thus produces activities in accordance therewith. To use a clumsy illustration let us suppose a still body of water in which the sun is shining—there is but *one* reflection of the sun. Let something stir the body of water so that a portion of it is sprayed into the air as a thousand drops, and in each drop we find the reflection duplicated. In the same way the one suggestion accepted by the subconscious mind

is apparently multiplied and reproduced in each cell of the body. In this way we believe that there is a direct mental influence upon the cells, independent of the benefit of the increased circulation and nerve currents. In fact, it may be possible that the increased circulation and nerve force is directed toward the part *because the cells demand it* by reason of the activity aroused within them.

In some forms of mental treatment there appears to be a "short-circuit" established directly between the mind of the suggestor, and the minds in the cells. In such cases the suggestions are directed to the affected parts, in a peculiar manner which shall be described in a later chapter. Some claim that this is but a masked form of plain suggestion, but we have seen results obtained by this method which seemed to render possible, or probable, the existence of some direct connection or "short-circuit," such as we have described. We shall not argue this point, for theories make but little difference in the practical work. We shall now proceed to a consideration of the several best methods for applying Suggestive Therapeutics. By applying these

methods you will be able to secure results from which you may deduce your own theories, or adopt those which seem to best fit the facts of the case. Long experience has caused us to regard any and all theories as but working hypotheses, to be applied in action. The final theory is probably still a long way off.

CHAPTER XIII.

THERAPEUTIC SUGGESTION.

The methods of application of Suggestive Therapeutics are as numerous as the many practitioners, for nearly every practitioner employs a method or methods of his own, based upon what he has learned and modified by his own experience. Each practitioner has some favorite method which is generally a modification of that of his teacher or teachers, the modification being determined by the result of his own experience, his temperament, his general philosophy of cure, and his previous training. But the underlying principle is the same. The practitioner who has received the regular medical training is very apt to mould his suggestions along the lines of his previous practice, with a tendency toward *placebos* or harmless preparations with which the suggestions are mingled. The giving of a number of small pellets accompanied with the suggestion that they will produce certain effects is a very effective form of Sug-

gestion, particularly if the patient has been accustomed to drugs and inoculated with a belief in the wonderful potencies of strange decoctions. In the same way a flavored fluid, taken at intervals of a half-hour, with the suggestion that certain results will follow, is a strong medium of Suggestion. Some practitioners give electrical treatments accompanied with strong Suggestions that certain physical changes will occur—and they get results. Others employ manipulations, rubbings, and similar methods, accompanied with strong Suggestion. In fact the suggestive accompaniment may be, and is, employed to advantage in almost every form of treatment. The knowledge of the potency of Suggestion gives the physician the key to the effect of many remedies which some physicians use with excellent results, while others find valueless. A drug, *plus Suggestion*, is an entirely different thing from the same drug, *minus Suggestion*. It is very difficult to determine the exact therapeutic value of any remedy, unless the element of Suggestion in its application be carefully weighed and considered.

If the practitioner happens to belong to any

of the various metaphysical or "New Thought" cults or schools, he will naturally model his suggestions along the lines of his belief. He will urge upon the patient certain teachings of his school, and if the patient be impressed by his earnestness and belief an excellent therapeutic effect is obtained. This idea, however, is vigorously opposed by many of the metaphysical practitioners, who hold that the healing is accomplished by reason of the virtue of their various dogmas, beliefs, and formulas—the proof of the same being apparently established by the number of cures obtained by them. "Our beliefs, dogmas, or theories *must* be so," they say, "else how could we obtain these wonderful cures?" This would be all very well, were it not for the fact that some other healer, with dogmas diametrically opposed to those of the first one, obtains cures of precisely the same nature, and in about the same percentage. The unprejudiced investigator is compelled to believe that the cures result, not from any special virtue residing in the several forms of metaphysical belief or theory, but simply because the patient's faith and expectant attention is

aroused by the practitioner, and an unconscious arousing and directing of his own mental energy is obtained by reason thereof.

Anything that serves to inspire confidence and faith in the patient, also serves to turn his mental forces to the affected part in the direction of a stimulating influence and corresponding improvement. The healing force is inherent in the mind of the patient himself,—all the healer can do is to direct it to advantage. Some forms of metaphysical healing are better adapted to certain patients than are others; but other patients must seek other forms best adapted to their temperament, prejudices and training. This fact is known to, and accepted by advanced students of scientific Suggestion, although disputed by the advocates of the many schools and cults. It is a very simple thing when it is considered in the light of reason. Schools A, B and C, have dogmas, doctrines and formulas diametrically opposed to each other. If one be right, the others must be wrong. And if the healing is dependent upon the virtues of the belief, theory or formulas, then it would follow that none but the *true* school could obtain results.

But what are the facts of the case? It is admitted by all scientific investigators, *that all of the three* will obtain the same kind of cures, in the same percentages, providing the practitioners are equally adapted for the work, and suited to the temperament of the patients.

No one who has ever studied the subject will deny that Dowie obtained many wonderful cures—but who would think of ascribing them to any special virtue in his methods or dogmas? Outside of his band of followers his claims are seen to be ridiculous. *Yet he made his cures.* Why? Because he obtained a Suggestive effect by reason of the belief, confidence, and expectant attention he aroused in his followers. Students of Suggestion who attended many of Dowie's healing meetings saw the most active employment of Suggestion in every process of the healing. Of course Dowie denied this, and abused those who so held. He claimed that he was inspired by God, and that God did the healing through him—Suggestion, he held, was the work of the Devil, and was but an imitation of the true method, just as the Egyptian magicians produced snakes in imitation of those produced by

Moses. He claimed that just as Moses' snake swallowed the others, so would Zion swallow the imitators. But it didn't!

In the same way the various leaders, teachers, and practitioners of the various cults, each claim that their way is the Truth, and that all others are base imitations. They are often forced to admit the cures of the rival healers, but they have the habit of saying: "Oh, well, they may *seem* to cure; but their cures won't last—ours alone will be permanent;" or: "others may *cure,* but we alone *heal.*" In short, they claim to have the only real article—all the others are imitators. They are like the Bowery second-hand clothes dealer, who put up the sign: "don't go to my imitators to be cheated—*come to me!*" But gradually the public is beginning to awaken to the truth that the real healing power resides within the patient himself, and that *any* method that serves to arouse that inherent power will tend toward the cure. *The method that is capable of arousing that power to the greatest degree, is the best method for that particular patient.* When this fact is recognized, it will be seen that each and every

school and cult has its particular place, and reaches certain people as no other form could do. The recognition of this fact should disarm the conflicting factions and cults, and cause them to see good in each other. There is need for a greater tolerance, broadness and charity in the various cults.

To give you an idea of how some of the metaphysical cults employ masked Suggestion in their healing work, we shall quote several of their "treatments." The student, who has grasped the underlying principle, should have no trouble in discovering the seed of Suggestion in these "treatments." These "treatments" are but the capsule, or sugar-coated pellet, in which the remedy is concealed. But remember this, always, that many people need the capsule, and the sugar-coating—they would refuse to accept *straight*, undisguised, and undiluted Suggestion if it were offered to them.

The following treatment for *nervousness*, is followed by a certain cult: "I am *warmed* and fed and clothed and *healed*, by Divine Love." This the patient is instructed to "repeat over and over" many times during the day. Surely

it is calculated to produce a restful and peaceful feeling in one of a strong religious temperament. Another "treatment" for Sore Feet, used by the same cult is as follows: "My feet can never be weary nor sore. God created my feet perfect. I walk the pathway of life in perfect ease and comfort. All the obstacles in my path have vanished, and my feet are bathed in a sea of pure love." The patient with the sore feet is instructed to "Mentally place yourself in an attitude to realize the power of the words you utter, for the fulness of peace and harmony in your feet comes with realization. The more frequently this spiritual medicine is used, the sooner comes manifestation of perfect health." Surely a soothing, restful suggestion,—and please note the *repetition.*

The following "healing affirmation" was used by a certain cult at its regular meetings, the congregation repeating the words after the leader: "With reverent recognition of my birthright, I claim my sonship with the Almighty. I am free from disease and disorder. I am in harmony with my Source. The Infinite Health is made manifest in me. The Infinite

Substance is my constant supply. The Infinite Life fills and strengthens me. The Infinite Intelligence illumines and directs me. The Infinite Love surrounds and protects me. The Infinite Power upholds and supports me. I am out of bondage. I have the freedom of the Sons of God. With all that is in me, I rejoice and give thanks. God and men are the all in all, now and evermore." It may be seen that the above "affirmation," made slowly and solemnly, accompanied by the religious environment, is calculated to bring relief mental and physical. But still it is Suggestion.

The following "treatment" has been used for Constipation, and Delayed Menstruation, by one of the cults: "All the natural channels of my body are open and free. The substance of my body is good." The following "treatment" for General Health is used by one of the cults: "What is true of God is true of man. God is the One All, and is always in a state of wholeness. I, the man of God, am always whole, like unto the One-All. No false belief environs or limits me. No shadow darkens my mental vision. My body is a heavenly body, and my eyes do behold the glory of God in all

visible things. I am well, and provided for, thank God, and nothing can make me think otherwise." The student of Suggestion recognizes and acknowledges the effect of similar suggestions upon those whose temperament inclines them toward this form of treatment. The fact of the cure is understood and admitted, while the theory is also understood.

The Emmanuel Movement uses similar "treatments," but unlike the cults and metaphysical schools, or many of them, it freely admits the nature of the force used. It acknowledges Suggestion, instead of denying it. It says, practically, "The healing power is inherent in the patient; Suggestion is the method of employing that power; and our treatments are among the better ways of arousing that power."

Other cults and schools pursue the radical method of instructing the patient to *deny absolutely* the existence of the disease, pain or disorder. The theory is that as God is Good, and as all things come from God—therefore anything that is *not* Good cannot come from God, and therefore must be a false belief or illusion. The "treatment" consists in deny-

ing away or repudiating the "false belief," "error" or "claim" of the mortal mind. Without entering into a discussion of the metaphysical, or theological points mentioned, the student of Suggestion sees that these "denials" of the trouble, and the "affirmations" of health and wholeness, must exert a mighty suggestive effect upon the patient who believes. Fear is removed, and Hope takes its place. These treatments have a well recognized value in the catagory of Suggestion, in spite of the theories and dogmatic conceptions of the cults and schools employing them.

The student of Suggestion perceives, very soon, that anything that tends to produce a hopeful, optimistic mental attitude, in place of the mental state of fear, pessimism and despair, has a decided therapeutic value along the lines of Suggestion. Fear is a negative mental state and is recognized as a powerful depressant of the physical activities. Hope is most positive, and is a mighty invigorant of the physical activities. Confident Expectation is a mental state most conducive to a manifestation of the desired and hoped-for physical condition. Any system of *materia*

medica, metaphysics, or religion, which is able to let in the sunshine of Hope, Optimism and Confident Expectation of Good, and which thus drives out the darkness of Fear, Pessimisim and Confident Expectation of Evil—has an important place in the category of Suggestive Therapeutics, no matter under what name it may masquerade, or upon what theories, beliefs, dogmas, or ideas it may rest. Its pragmatic value is determined by "What does it do—how does it work—how does it 'make good' in action?"

CHAPTER XIV.

SUGGESTIVE TREATMENTS.

In contrast with the practitioners of Suggestive Therapeutics who give their suggestions under the forms and by the methods of the various metaphysical cults on the one hand, and those who give "masked suggestions" in the shape of *placebos,* harmless drugs, etc., on the other hand, there is to be found a large and constantly increasing number of practitioners who confine themselves to the practice of Suggestive Therapeutics, pure and simple. While the various methods of applying Suggestion varies according to the respective views of the practitioner, still there is to be found a general underlying basis of application in all of such cases. We shall now ask you to consider the general method of suggestive treatment followed by this school of healing.

In the first place the practitioner of Suggestive Therapeutics, pure and simple, does not attempt to "deny" the existence of the

disease or disorder. Nor does he claim that the cure is due to any occult power or metaphysical belief. On the contrary, he bases his treatment upon the recognized laws of psychology, and physiology. He first endeavors to diagnose the cause of the trouble—not the symptoms, but the *cause*. This step being accomplished, he then endeavors to gain the confidence of the patient by a careful talk, and then directs his suggestions in such a way as to bring about a return of normal functioning of the cells, organs and parts of the patient. In order to do this he forms the mental image of *the healthy individual*, and endeavor to bring up the patient to that ideal. Instead of studying diseased conditions, he studies the conditions of normal health and then tries to bring up the patient to that standard by an appropriate line of Suggestion.

This process is not so intricate as it might appear at first thought, for, as a rule, the abnormal condition has been caused by a neglect of some of the rules and laws of normal living and thinking. A correction of these bad habits of living and thinking may be brought about by firm and repeated suggestions that

the patient will act and think otherwise. In the majority of cases seeking suggestive treatment, there will be found a chronic condition of imperfect nutrition, digestion, assimilation, and elimination. This condition manifests itself in a poor circulation, weak digestion, nervousness, constipation, and general run down state of health. These cases are called "typical cases" requiring this form of treatment. The patient as a rule has a "weak stomach," cold hands and feet, poor circulation, nervousness, and is more or less constipated. If the patient is a woman, she is also apt to have menstrual troubles. In order to relieve this condition, the practitioner aims his suggestion directly toward starting correct habits of living, and in this way strikes right at the heart of the original cause of the trouble. Perhaps the best way to explain this to you, would be to give you a general outline of the treatment of a "typical case" of this kind, by a practitioner of Suggestive Therapeutics.

The treatment commences with a careful examination of the patient's condition; the securing of the history of the case; general symptoms, etc. This done, the practitioner

tells the patient that he must not dwell upon the past history, nor upon the symptoms—he has come to a parting of the ways, and must "forget" the old troubles and leave them behind him. He then informs the patient that he must allow the suggestions to sink into his subconscious mind, there to take root and then manifest in physical conditions. Bidding the patient to assume a position of restful calm, he begins to give him suggestions, in a firm, quiet, but positive tone, with frequent repetitions of the vital points. The following will give a general idea of such a treatment:

"You are now resting, quietly and calmly, with a mind open to the inflow of strong, helpful suggestions, which will build you up gradually and surely into a condition of health. These suggestions will bring to your bodily cells and organs a normal healthy condition, in which they will be able to do the work that Nature intended them to do—and they *will* do it—they *will* do it. In the first place, we shall cause your stomach to act properly and digest the food that you place in it to nourish the body, and which shall be assimilated and distributed in the shape of rich good blood to

every part of your body—every part of your body—there to do its work of building you up—building you up to strong vigorous health. You have cast aside all fear, and from now on will look forward confidently and expectantly toward the return of health. You will find that your appetite for nourishing food is returning—you will find that a normal healthy hunger will return to you, beginning from this minute. You will begin to crave nourishing food, and such food will be well taken care of by your digestive organs. You will masticate your food thoroughly and slowly, thus gaining every particle of nourishment from it, and rendering it easily digested—you will masticate your food thoroughly from now on. Your saliva will prepare your food for your stomach, therefore you will masticate thoroughly each mouthful of food that you eat hereafter—each mouthful will be well masticated hereafter. Thus will you prepare it for the action of the gastric juices which will flow freely in your stomach, from now on, and which will thoroughly digest every particle of the good nourishing food for which you are beginning to hunger already. Your stomach is strong,

strong, strong—strong and able to take care of the good nourishing food that you shall give it hereafter, because you will be hungry for it. The stomach will digest this food thoroughly, and the nourishment therefrom will be thoroughly assimilated and converted into rich red good blood, which will be carried to all parts of your body—to all parts of your body, there to build you up—to build you up, to health and strength.

"The body is built up from the nourishment obtained from good healthy food, for which you now feel hungry, and which you will digest easily. From to-day you will find yourself eating and digesting like the normal healthy person—for you *are* that normal healthy person, from now on. You will increase in health and strength every day, from now on. You will drink a sufficient quantity of fluids each day, for Nature requires these fluids in order to provide the various liquids of the system—the blood, the gastric juices, and the bile—all these things mean that you must increase your fluids. You will increase your fluids until you will drink nearly two quarts of water during each twenty-four hours

—this is the normal amount for the healthy man or woman, and you will soon learn to *want* this quantity. You will also begin to breathe fully, drawing in a few deep breaths every few hours. The air provides oxygen which invigorates and purifies your blood as it passes through your lungs. You will find that this deep breathing will make you feel strong and vigorous. You will find that you will begin to take a new interest in life, and will want to walk in the fresh air as Nature intended you to do. You will find that the increased fluids will tend to restore a normal movement of the bowels, and from now on you will be regular and natural in this respect. Your nerves will grow strong, and you will feel young and vigorous, and full of life. In short, from now on, you will begin to grow steadily and surely to be *a healthy human being,* such as Nature intended you to be. This is your birthright, and you are now going to claim your own. Health is the natural state, and you are going to be natural from now on. You will throw aside all worry and fear, and from now on will become a healthy, cheerful, bright and happy person."

In the case of a woman patient, the suggestions also include normal functioning of the organs peculiar to the sex. In case of any special troubles, appropriate suggestions are also given, but in all cases the fundamental suggestions are included, for upon the restoration of natural normal functioning of the entire body depends perfect health, no matter what may be the special complaint.

In reading the above "typical treatment" the reader will be struck with the fact that these suggestions are all directed toward the conditions *which are desired,* rather than toward the eradication of the undesirable ones. This is in acordance with the fundamental principles of The New Psychology, which hold that negative conditions are best eradicated by the cultivation of the positive ones. Health is positive, disease negative—in building up the positive the negative disappears. Disease *is not a thing*—it is merely the negation of Health. Disease is like darkness, while Health is like light—turn on the light and the darkness has disappeared. This is the one great distinguishing feature of Suggestive Therapeutics—it looks toward the healthy condi-

tion, rather than upon the diseased ones. By keeping its eyes and thought fixed on the positive conditions, it tends to dissipate the negatives. The practitioner of Suggestive Therapeutics studies *the healthy man,* rather than the diseased one. His mind is ever filled with the thoughts of Health, and he endeavors to set up a corresponding mental image in the minds of his patients. He steadily refuses to even *talk* disease,—his talk is ever along the lines of health. The normal attracts him, not the abnormal. This in itself is a great step in advance in practice of any and all healing methods, and will undoubtedly be the "mental attitude" of practitioners of every school in the future.

It is impossible, of course, to give detailed instructions for treatment in a book of this kind, for such would be foreign to its general purpose. But, nevertheless, we have given you here the fundamentals of the best general treatment along the lines of Suggestive Therapeutics—you may alter, add, change, or modify them to meet the requirements of a variety of cases. The main point to be remembered is that confidence begets power,

and that your suggestions should always be directed along the exact lines of physical change that you desire to produce. When you wish a boy to sit down, you bid him do so—follow the same plan in "talking to" the bodily organs, cells or parts. In this connection, read the next chapter.

CHAPTER XV.

"THE NEW METHOD."

In addition to the methods of applying Suggestive Therapeutics mentioned in the preceding chapters, in which the cells, organs and parts of the body are reached through the general subconscious mind of the patient, there is another form in which the suggestions are directed immediately to the cells themselves. This method while far from being favored by the majority of the authorities on the subject, and open to the objection of being but "masked suggestion" in which the apparent direct application is by a fanciful form of arousing the activities of the cells via the subconscious mind, nevertheless has attracted great attention from a number of earnest experimenters who have obtained very satisfactory results through it, and is therefore worthy of respectful consideration.

The theory underlying this direct method of applying Suggestion to the cells and organs, is based upon the general working hypothesis

of the existence of mind in the cells and parts, which "mind" is capable of becoming aware of the desire, will or mental pictures (or whatever we choose to call it) in the mind of the person giving the suggestions. In other words the cells or parts may be made "conscious of" or "aware of" the state of mind of the suggester. It is not necessary to indulge in any special metaphysical theory or belief regarding the nature of these "cell-minds," in order to practice this form of healing. It is sufficient for the purpose to rest content with the pragmatic idea that "it works"—that is, that the application of the method in question tends to arouse the cells, organs or parts in renewed activity and normal functioning. While the effect of this method of Suggestion is heightened by the employment of words, it is not necessary to assume that the cells or organs "understand" the words—the probability is that the words serve merely to intensify the mental state of the suggester, and to enable him to concentrate his mind upon his work.

But whatever may be the explanation of the method or means whereby the cells, organs or

parts become "aware" of the intentions and desires of the suggester, experiments seem to show that they *do become aware* of the same, and respond thereto in varying degrees. Moreover, the cells, organs and parts seem capable of being trained to become sensible of the suggestions, and to respond thereto in a greater measure. Waiving all theories or "explanations," it may be said that the cells, organs and parts of the body *act as if they were aware* of the treatment being given them, and the suggestions being directed to them. Whether we assume that there is a direct channel of communication between the mind of the suggester and the cells, organs or parts; or whether we fall back upon the idea that the channel is really through the general subconsciousness and that the direct suggestions operate merely as a striking method of applying Suggestion through the ordinary channels, the fact remains that in giving and taking these treatments excellent results may be obtained by assuming, even conditionally, that the cells, organs or parts are "entities" capable of understanding the suggestions and responding thereto. And, whatever may be the

details of the real reason of the process, the general fact remains that there *is* mind in the cells, organs and parts, that is somehow, someway, aroused and which responds to the suggestive influence.

The method of application of this form of Suggestion is simplicity itself. All that is necessary is that the suggester arouse the attention of the cells, and then address them as if they were entities. These cells or organ entities vary in degree of "intelligence," not only so far as is concerned the differences between the personality of their owners, but also in the matter of differences in themselves. The cells in the liver differ from the cells in the heart or stomach for instance. These cell-minds resemble the minds of children—very young children, in fact. There must be something done to arouse their attention, and then to hold their interest. This being done, they must be "spoken to" authoritatively, and firmly, with constant repetition and insistence. They must be told what to do, and they must be held up to their work by insistent command and demand. The successful practitioner of this form of Suggestion must needs possess

and display many of the characteristics of the successful school-teacher of the lower grades. In an earlier work on this subject, we said: "The way to reach the mind in the cells, cell-groups, ganglia, organs, nerves, parts, etc., of the body, is to *address yourself directly to it, just as you would to a person.* You must think of the mind in the affected part, as a 'person' who is misbehaving. You must remonstrate with, argue with, coax, order, or 'drive' the 'person' residing in the organ, just as you would different individuals. Sometimes coaxing is much better than driving, and sometimes the forceful method is necessary, as we shall see. You may either talk aloud to the mind in the organ, or else (and this is the better way in treating others) you may do your talking mentally. Tell the cell-mind just what you expect of it—just what you intend it shall do—just what is right for it to do, etc. *And it will obey.*" In this statement is contained the essence of this method of applying Suggestion. The rest is merely a matter of detail.

In this form of treatment, many practitioners begin by using the hands to tap lightly

or sharply over the affected organ or part, which seems to arouse something akin to attention. This seems to be needed particularly at first until the cells "get used to you." The idea seems to be akin to that put into effect when we tap a man on the arm or shoulder, to attract his attention from the many sights and sounds around him. It is as if we tapped over the organ, saying "Here you! Wake up! Listen to me!" in a firm authoritative manner. It is like the tap of the gavel on the speaker's desk in Congress—or the tapping of the teacher's gong in school—or the military command of "Attention!" It operates precisely in the same way, and in the same way there is noticed an acquiring of the habit of coming to attention on the part of the organ or cells, after a few treatments. Personally, we are of the opinion that the use of the hands in certain forms of treatment has a similar effect, and that much of the after details of these various manual treatments act along the lines of Suggestion.

After having aroused the attention of the cell, organ or part, the suggester proceeds to "talk to" it, using forcible suggestions. Quot-

ing from our former work referred to: "A plain, simple way of giving this treatment is to awaken the attention of the mind in the cell, organ or part, as above stated, and then proceeding to mentally lecture it, calling it by name, as for instance: 'Here, Stomach!' or 'Now, you Liver!' etc. Don't smile at this advice—just try it on yourself, and you will stop smiling. *Then go on and tell the Organ-Mind just what you would tell it if it were an actual personality—a childish mind for instance.* You will soon find how quick the organ-mind is to awaken to your words, and to act upon your suggestions or orders. Follow the law of Suggestion in giving these treatments to the organ-minds—that is, remember the suggestive phases of Repetition, Authoritative Demand or Command, etc. Don't be afraid, but start in to give the Organ-Mind a 'piece of your mind,' and it will obey you. . . . There are no fixed forms of treatment along these lines. You must acquire the 'knack' by practice. The proper words will suggest themselves to you. The thing to do is to know what you want done, and then to command the organ-mind to do that thing; using

the same words that you would use in talking to a real person in the place of the organ. You will soon acquire the art, by a little practice. Those who have treated a large number of persons in this way have told me that the mind in the organs and parts seem to instinctively recognize the healer's power over them. Just as a horse or dog will recognize men who are accustomed to managing animals of their kind, so will these organ-minds recognize their master in one who has practiced the art of healing along these lines."

All who have practiced this form of Suggestive Healing, bear testimony to the fact that there are great differences in the degrees of "intelligence" in the various organs, and also great differences in the "nature or disposition" of the various organs. For instance, the heart is found to be quite "intelligent" and amenable to reasonable suggestion, encouragement and control. The liver, on the contrary, is always found to be a heavy, sluggish, stubborn, mulish, obstinate entity, which yields only to sharp and vigorous commands and driving. As one person once said to us: "The liver is a mule, and must be treated as

such''—and we agree perfectly with this statement. There is just as much difference between a spirited horse, and a mulish mule, as between the heart and the liver. Accordingly there must be a difference in the treatment applied to these parts. The one needs but a little gentle patting and urging, while the other needs ''the big stick.'' The stomach occupies a position between the two—possibly the position of a draught-horse. When not brutalized with stuffing and over-work, the stomach is a very faithful, hard working organ. It has a tendency to become frightened at adverse suggestions, and is rendered weak by fear. But it may be encouraged and restored to normal functioning by this method of treatment. It responds to trust, encouragement and reassurance, and has a desire to perform tasks expected of it, if fear is taken away from it. A peculiar thing about the stomach is that it seems to like ''jollying'' or ''flattery''—tell it how good a stomach it is, and how well it can do its work; and how much you trust it to run things right for you; and lo! it proceeds to make good, and to justify your praise and commendations.

The nerves respond readily to this form of treatment, along gentle coaxing lines. The circulation of the blood may be increased in certain parts, or restrained, in this way. In this way the blood may be swept all over the body, creating a pleasant glow; or it may be drawn away from an aching head, or a feverish brow. The bowels respond readily to a firm, kind treatment, in which they are told to move regularly—it being well to name a certain time at which you expect them to establish a regular habit, *in which case be sure to keep your appointment with them, and give them a chance.* The organs peculiar to women will respond readily to this form of treatment. Regular menstruation has often been established by treatments of this kind, given a month ahead, and keeping it up every day until the regular period—in this case the fixing of a date being an important detail. Suggestions of "Firm, now, firm and strong" have relieved many cases of weakness of the uterus. Profuse menstruation has yielded to the commands of 'Slow, now; easy; easy; not to free a flow' etc."

The method considered in this chapter may

be applied either along the lines of ordinary Suggestion given by one person to another; or along the lines of Auto-Suggestion or self-treatment, in which the suggestions are given by the person himself direct to the minds in the cells, organs or parts—just as if one were treating another person.

PART III

AUTO-SUGGESTION

CHAPTER XVI.

AUTO-SUGGESTION.

By "Auto-Suggestion" is meant the application of the principles of Suggestion *by oneself upon oneself.* In Auto Suggestion the individual plays the dual role of suggester and suggestee, respectively. In all other respects it is precisely the same thing as Suggestion in its general phases. In Auto-Suggestion may be found the Suggestion of Impression, the Suggestion of Induction, the Suggestion of Association, which are found in the ordinary phases of Suggestion. In Auto-Suggestion may be noticed the five phases of Suggestion, viz: Suggestion of Authority, Suggestion of Association, Suggestion of Habit, Suggestion of Repetition and Suggestion of Imitation, respectively.

It may seem strange to think of one's suggesting to oneself "with authority," but it is true that if one will use the authority of his will he may impress upon his subconsciousness such suggestions as he may wish to place

there, and may thus *make over his entire character,* or develop within himself the qualities which he may desire. In the same way he may force associations upon his mind by Suggestion, and thus produce the same effect upon himself as those produced by associative suggestions from without. One may suggest habits of thought, action and feeling upon himself, just as truly as habits may be induced by suggestions from without. As for the Suggestion of Repetition, it will be found that this phase of Suggestion plays a most important part in Auto-Suggestion. Even Suggestion of Imitation plays its part in Auto-Suggestion, for one may suggest to himself that he will imitate others; emulate them; pattern after them; model upon them; if he so desires. In short, in Auto-Suggestion we find that we have Suggestion in all of its many phases and forms, the only difference being that the individual gives the suggestions to himself, instead of receiving them from outside sources. The study of Auto-Suggestion is really the study of Suggestion.

Those authorities in The New Psychology who analyze things to their ultimate elements,

rightly hold that the active principle of all Suggestion is really Auto-Suggestion. That is to say, that the active force manifested in Suggestion, is really called into play by the individual himself, usually involuntarily. When we accept a suggestion from outside, we allow it to pass the portals of our reason and judgment into the workshop of our will, there to set into motion the machinery of our mind. We allow our reason and judgment to neglect their duty, and to thereby admit undesirable strangers to our mental workshop. In Auto-Suggestion, as the term is generally applied, we voluntarily select and choose the suggestions which we wish to impress us, and we add to their effect by repetition and attention. But in both Suggestion and Auto-Suggestion the principle employed is precisely the same. The power is entirely within the mind of the person himself, although it may require the assistance of some outside person to call it into effect. The Suggestionist drives away fear and inspires confidence and expectant attention, and then leads and directs the will of the patient in the direction of performing the physical cure. Or he uses Suggestion in

one or more of its phases, in order to induce the person to accept and believe what he says or does, and thereby gains the same effect as if the person had reasoned out the matter and impressed it upon his own mind. Suggestion from outside is the use by another of one's mental tools and machinery; while Auto-Suggestion is the use of the same tools and machinery by oneself.

It is difficult to draw a dividing-line between the phenomena of Suggestion and that of Auto-Suggestion—they blend into each other in many subtle degrees. For instance, one may receive an impression from outside —an impression which is the effect of a suggestion from outside—and being impressed by it, he may think it over and think and feel about it, so that the idea takes a firm hold upon him. Up to this point it is Suggestion in its general phase. But, then he repeats the suggestion to himself, both in self-communion and in conversation with others, until he has made an impression much deeper than that caused by the original impression. This secondary effect is Auto-Suggestion, of course.

There is another form of Auto-Suggestion

which is overlooked by many of the authorities. We refer to cases of involuntary Auto-Suggestion—cases in which the person impresses suggestions upon himself without intending to do so. We may illustrate this last mentioned phase by the tale of the man who tells a "fish-story" so often that he gets to believe it himself. Although the story may have had but little basis in fact, the constant, earnest repetition of it with the intention of impressing it upon others, acts as a repeated Auto-Suggestion which impresses itself upon the subconscious mind until it becomes a fixture there. Everyone who reads these words will be able to recall cases of this kind in his own experience.

The above mentioned form of Auto-Suggestion finds an illustration in the cases of many men whose business or profession finds them engaged in exploiting certain sophistries or half-truths, which are so known to them in the beginning—these tales told repeatedly for a period of time become actual truths to these persons by reason of Auto-Suggestion, and they fall victims to their own suggestive power. There are many instances of charla-

tans and religious imposters who finally fell victims to their own repeated suggestions, coming to actually believe the tales which they invented to impress others. We have a personal knowledge of a case in which an owner of a celebrated patent medicine purporting to cure nervousness, and who wrote his own startling advertisements in which he claimed all symptoms as indicating "nervousness," finally falling a victim to his own suggestive imagination and becoming a hypochondriac filled with fears of "symptoms" and possessed with the idea that he was a nervous wreck.

We believe that a celebrated religious imposter, now dead, fell a victom to his own claims of divine inspiration and power, and became mentally unbalanced by reason thereof. In fact, it is a common and well-known fact in the history of "new religions" that many of the leaders of such movements become mentally unbalanced by the constant repetition of their tales of "inspiration," "special divine guidance" and the rest of it. Writers along special lines often have a hard fight to avoid being overcome with the Auto-

Suggestions made easy by reason of their constant statements of certain special things. Experts on insanity frequently become insane. Writers upon certain forms of disease are often affected by their own statements, constantly repeated. Salesmen become impressed with certain tales told about their particular goods, that if they happen to change employers the old Auto-Suggestions are very hard to overcome. Fanaticism and bigotry arise often from the constant statement of certain beliefs to others, acting as Auto-Suggestion. In short, that which we constantly repeat to ourselves, and others, tends to become a fixed impression in our minds, difficult to eradicate, and often influencing us to a great extent. This being the case, we should avoid influencing ourselves along these undesirable lines, and should always try to impress ourselves with desirable qualities and ideas. We have the power of intelligent choice in this matter—there is no excuse for not using it properly.

Many of the cures claimed by Suggestion in its many forms, are really due to the Auto-Suggestion of the patient, pure and simple. Of course *all* mental cures have the element

of Auto-Suggestion largely in evidence, but in some cases we can say that Auto-Suggestion does *all* the work. For instance, we have frequently heard mental healers relate cases in which patients wrote to them for "absent treatment," and received results even before the healer received the letter requesting treatment. Leaving out of the question, entirely, all discussion of the virtues, merits and explanation of "absent treatments," it must be admitted that in the cases mentioned *there was no "absent treatment" whatsoever* at the time, and that the entire benefit arose from the Auto-Suggestion of the patient. In one case the healer tells that the patient's original letter was misdirected and went astray, and that the first that the healer knew of the matter was the receipt of a second letter, a month later, in which the patient testified to the wonderful effect of the "month's treatments" that she supposed she was receiving. The cure was not an imaginary one either, for investigation revealed a case in which the physicians held that there was a chronic condition beyond cure, and that the patient had been perfectly restored to health.

Of course, we have heard of "explanations" of these cures, to the effect that in some way the "subjective mind" of the patient seeks the "subjective mind" of the healer, in the ether, and there receives the "treatment." This may be all true—we cannot prove that it is not; but Auto-Suggestion affords a much simpler explanation. If the patient had pinned her faith on the bones of St. Anne, or some other object, to the same extent that she believed in the healer, she would have received the same result—all experience and investigation proves this. These cases bear all the evidences of cases of Auto-Suggestion.

In this connection, we may add that the recital of these cases, and the "subjective mind meeting" in the ether, has injured the business of certain absent healers, for their patients finding that they can receive this "subjective mind" treatment without paying for it in the regular way, now do not write to the healers at all, but simply make the "etheric" connection, and receive the treatment (?) free of charge and without the knowledge of the healers. Surely this is a case of psychic "wire-tapping" needing the attention of the

authorities! To the student of Auto-Suggestion all of these wonderful things are found to be very simple at the last analysis, and to rest upon the firm foundation of pure psychology. And in the same category may be placed the strange cases which the scoffing public would dismiss as "only imagination." Auto-Suggestion is a potent force, which works great harm to persons who misuse it, or who use it ignorantly; but which is equally potent for good when rightly and intelligently employed. It is a most valuable mental instrument or tool, with which we may make of ourselves what we will. It lies very close to the heart of The New Psychology.

CHAPTER XVII.

SELF-IMPRESSION.

As we have said in the preceding chapter, the person practicing Auto-Suggestion is both the suggester and suggestee. He plays a dual role, viz (1) the part of the teacher or master; and (2) the part of the pupil or scholar. Auto-Suggestion might well be called "Self Impression," for the latter term correctly describes the actual process. The objective "I" impresses the subjective "Me." The conscious region of the mind impresses the subconsciousness. This is the whole thing in a nutshell. The actual process is a case of "Sez I to meself, sez I."

It is astonishing how the subconscious mind may be trained to work for one by a scientific course of Auto-Suggestion or Self-Impression. As we have said in a previous work on the subject: "One may charge his subconscious mind with the task of waking him up at a certain time in the morning—and he wakes up. Or he may charge his mind to remember

a certain thing—and he remembers it. This form of self-mastery may be carried to great lengths, and one may bid his subconscious mind collect data regarding certain subjects, from amidst its heterogeneous collection of mental odds and ends of knowledge; and then bid it combine the information into a systematic form—and the mind will so act, and the combined information will be at hand when needed. I find myself doing this, almost unconsciously, when I start to write a book—fact after fact, and illustration after illustration, appearing at their proper time and place. The field of Self-Impression or Auto-Suggestion, and the workings of the subconscious mind, have just had their outer edges explored—there is a great field of mentation here awaiting some of you."

Auto-Suggestion may be considered in several phases, although the underlying principle is the same. In the first place every person has filled his mind with a number of involuntary Auto-Suggestions arising from the repetition of suggestions and impressions originally received from outward sources. These Auto-Suggestions are harbored in the shape of

prejudices for and against persons or things; certain fixed beliefs not based upon reason or actual judgment or experience; certain arbitrary associations; and other results of previous impressions which have become firmly fixed by repetition along the lines of Auto-Suggestion.

Another phase is that in which the Auto-Suggestion is given and accepted tacitly or by implication, as when one takes a certain medicine believing that it will produce a certain result, in which the suggestion is transformed into Auto-Suggestion by the belief of the person. For instance if your friend gives you a powder saying that it will tend toward improved digestion, and you believe him—then when you take the powder you will have the following idea: "This powder will settle my stomach and cause me to digest my dinner perfectly." Although the idea may not be uttered in spoken words, nevertheless there will be the verbal Auto-Suggestion. In the same way you may give yourself an implied adverse Auto-Suggestion regarding fresh air, or certain foods, and the result is that you experience a bad effect. This form of Auto-Sugges-

tion consists in a *firm belief* on your part that certain things will produce certain results, or that certain things possess certain qualities, etc. Every one has a goodly stock of Auto-Suggestions of this type, which exert a greater or less effect upon his character and actions. Carried to extreme, they produce fanaticism, bigotry, fixed-ideas or even monomania. Lacking them, the person is apt to be more or less fickle, unsettled, changeable and uncertain. Much that we have called "principles" of conduct is based upon this type of Auto-Suggestion heightened by habit. The moral is obvious.

The third type or class of Auto-Suggestion is that form of impression which is deliberately and voluntarily impressed upon the subconscious mind by the conscious mind, with and for a particular definite purpose. For instance, you wish to catch a train tomorrow morning shortly after four o'clock; you deliberately charge your subconscious mind with the idea "awake at four o'clock to catch that train," and you find that you will awake from your sleep about that time. You "have it on your mind," and you awake. The subcon-

scious mind may be set like an alarm clock. In the same way a mother's subconscious mind will cause her to awaken at the slightest noise of the babe, while much louder noises will fail to arouse her. You have an engagement at three o'clock, and charge your mind with it, and a little before the hour you will find a certain mental uneasiness manifesting itself, and just before the hour the thought will flash into your conscious field of mind: "That engagement with Smith at three o'clock." It is this phase of Suggestion that is actively employed in the Character Building processes which form so important a part in the practical work of The New Psychology. The New Psychology teaches that one may build up any set of brain-cells by appropriate lines of Auto-Suggestion and resulting action, which will develop certain desired tendencies and characteristics. Also one may inhibit or neutralize certain objectionable traits or characteristics by deliberately building up the qualities directly opposed to those of which he desires to be rid. There is nothing occult or mystical about this process—it is based upon the scientific knowledge of the mind and brain.

This last mentioned phase of Auto-Suggestion plays an important part in the methods and practices of the many metaphysical cults and schools, including those of religious cults which use similar methods. The various "affirmations," "denials," "statements," etc., used by these cults and schools are but forms of Auto-Suggestion, and their results are obtained along its lines. Much good work has been accomplished by these organizations and schools in the direction of producing improved mental, physical and moral conditions. Many a person has been brought out of enfeebled and abnormal physical conditions; many a one has changed his mental states and character of thought; many a person's moral character has been improved by these methods. In spite of the extravagant statements and claims of some of the cults, there has been a great deal of good accomplished by them. They have replaced Pessimism with Optimism; Fear with Hope; Despair with Courage. But it is not necessary to accept any of their theories, dogmas, or creeds, in order to partake of the benefits of the "treatments," for an understanding of

Auto-Suggestion, and an intelligent practicing of its methods will enable any one to secure these beneficial results along purely scientific lines.

The one possible weak point of the various methods of applying Auto-Suggestion, and one which has not escaped the attention of the critics, is that unless the person understands the underlying principles, there is a tendency toward resting content with the mere "lip statement" of the Auto-Suggestion, and a neglect to manifest into activity and actual "doing" the desired quality or power. In the following chapters we shall endeavor to point out an improved plan of applying Auto-Suggestion, in which there is employed a correlated physical activity in connection with the use of the proper Auto-Suggestion.

To those who are repelled by the vague metaphysical conception of the cults, and who, while desirous of obtaining the benefits of the methods of Auto-Suggestion, demand some explanation along purely material lines, we would say that a little examination into the teachings of science regarding the nature and function of the brain will explain the work-

ing principle of Auto-Suggestion, along purely physical lines and without recourse to metaphysical theory. Science informs us that the brain is composed of a substance called "plasm," which consists of an enormous number of tiny cells which are used in the manifestation of thought. These brain-cells are estimated to number from 500,000,000 to 2,000,000,000, according to the mental activity of the individual. There is always a great number of reserve brain-cells remaining unused in every brain, the estimate being that even in the case of the most active brain there are always several millions of reserve brain-cells at any time. Science also informs us that the brain grows additional brain-cells to meet an increased demand. Brain-building consists of the development and growth of brain-cells in any special region of the brain, for the brain consists of various centres and localities, in which are manifested the various mental faculties, qualities or functions. By developing the brain-cells in any particular region, the quality, activity, or faculty which has that region for its seat is necessarily greatly increased and rendered more effective

and powerful. It is a fully demonstrated scientific fact that man may "make himself over" mentally, if he will but devote the same degree of attention, patience and work to the subject that he would in case of desired development of some part of the physical body—some muscle or limb, for instance. And the processes are almost identical in the case of muscle and brain-cells—use, exercise, and practice along the lines of Auto-Suggestion and its correlated activities.

CHAPTER XVIII.

AUTO-SUGGESTIVE METHODS.

The majority of writers and teachers of Auto-Suggestion confine themselves to methods similar to those of the cults and metaphysical schools, inasmuch as their methods consist almost entirely of certain more or less well-selected "affirmations," "statements," or auto-suggestions, which the person is expected to repeat to himself, with the idea of thereby impressing upon his subconscious mentality the idea back of the words. This, of course, is an important part of the true method of Auto-Suggestion, but there are other features to be included in order to obtain the best results. There is the danger of one becoming mechanical in the automatic statements of "I am *this*" or "I am *that*" of the affirmative methods. There is the tendency of the habit-mind to take up the affirmations or statements and to continue the repetition along automatic lines, similar to the meaningless repetitions of the parrot, or the

mechanical repetitions of the phonograph. In this way the affirmations fail to carry their dynamic force to the subconscious mind, and consequently the impressions cease to be clearly and distinctly made. The process becoming mere habit, is like the phenomenon of the mind refusing to be impressed by a continuous accustomed noise or sound, while alive to any variation therefrom. The affirmations must be made in a manner which will hold the attention and interest, and must also be accompanied by correlated actions, in order to become fully effective in the work of character building. There must be a seeing and doing, as well as a *saying*. The best impressions are made by (1) Saying; (2) Seeing; and (3) Acting and Doing. Let us consider this threefold method.

In the first place, we have always contended that there is a much better way of *saying*, or speaking the affirmation or auto-suggestion, than the familiar "I am *this*, or *that*." We have found that the nearer one comes to the perfect playing out of the dual role of suggester and suggestee, the better will be the result—the clearer will be the impression upon

the subconscious mind. Accordingly one should endeavor to "talk to himself" as if he were speaking to another person. He should endeavor to give his suggestions to himself, precisely as if he were suggesting to another person. Whatever may be the detail of the psychic operation, the fact remains that by so doing he will be able to obtain and register a much clearer, deeper and more lasting impression than by the "I am this, or that" form of affirmation. In fact, we think that the idea of "affirmation" may as well be discarded, first and last, in the practical work of Auto-Suggestion, and that the "I" of the person should actually *suggest* to the "Me" of himself. Let it be Suggestion, instead of *affirmation.*

In making these suggestions to yourself, you should always address yourself (when giving the suggestions) *as if you were speaking to a third person.* Instead of saying "I am courageous and fearless," you should suggest to yourself as follows: "John Smith, (here use your own name, of course), John Smith you are courageous and fearless; you fear nothing; every day you are gaining in

courage and fearlessness, and are getting stronger, stronger, stronger, etc." Do you get the idea? Try both methods now—stopping your reading for the purpose. Say as strong an "I am" as you can, and then try the effect of the strongest suggestion of "You are" addressed to your subconsciousness. Imagine that you are suggesting to another person whom you are very desirous of building up and strengthening. You will find a new field of Auto-Suggestion opening up before you. A little knack is required, but a few trials will show you the value of this improved method. Talk to "John Smith" as if he were an entirely different individual. Tell him what you wish him to do and become, and how you expect him to act. You will be surprised to see how obedient this subconscious mentality will become.

The following illustration, taken from one of our earlier works, will give you the idea of a "sample" treatment by Auto-Suggestion: "Suppose you wish to cultivate Fearlessness in place of the Fearthought that has bothered you so much, . . . you wish to use Auto-Suggestion. The old way, you remember,

was to claim to yourself 'I am Fearless, etc.' The new way of treating yourself is to imagine that you are giving a suggestive treatment to some other person, for precisely the same trouble. Sit down and give a regular treatment *to yourself,* imagining that you, the individual, are giving a treatment to the "Me" or personality—the Central Mind giving a treatment to the John Smith part of you, the personality. Do you see? The Individual (that's *You*) says to the personality of 'John Smith' (your subconscious self): 'Here, John Smith, you must brace up and do better. You are fearless, fearless, fearless! I tell you, you are fearless! You are courageous, brave and bold! You fear nothing! You are confident and self-reliant! You are filled with strong, positive mind-power, and you are going to manifest it—you are going to grow more and more positive every day! You are positive this minute—do you hear me? POSITIVE this very minute, I say; positive *this very minute!* You are positive, fearless, confident, and self-reliant, right now, and you will grow more and more so every day. Remember now, you are positive, positive, posi-

tive—fearless, fearless, fearless' etc., etc., etc. You will find that by this plan you will be able fairly to pour the positive suggestions into the receptive subconscious mind—and that the 'John Smith' part of you will accept the impressions just as if there were two persons instead of one." This is not childish nor mere play—it is a process based upon the soundest psychological principles. You will be surprised to find how readily you may "order yourself around" by following this plan for a while.

In the succeeding chapter, we will give you some Auto-Suggestions for specific cases, to be used along the above lines. Acquire the knack of suggesting to yourself, and you will have a great work of self-improvement opened out for you.

The second step in the improved method of Auto-Suggestion, consists of what has been called "Visualization," which consists of forming the mental image of yourself as possessed of the qualities which you wish to develop in yourself. The clearer mental picture that you can make of yourself, *as you wish to be,* the deeper and clearer impression will be

made by the accompanying Auto-Suggestion. The explanation of this lies in the fact that *ideals tend to materialize objectively.* It is a psychological fact that we tend to grow toward our ideals. An ideal is a mental pattern upon which is modeled our character, actions, and general life. Many a man has attained success in life by his faithful adherance to some great ideal held firmly in his mind. The thing that fills our mental eye is the thing towards which we move. This is recognized in all moral teaching and religion, although the psychological principle is not understood. The young are taught to take some great example as an ideal—some great figure in religious or secular history. The Christian is taught to model his life upon that great ideal of the character of the founder of his faith. The Catholic child is also taught to consider the lives of the saints, and the devout fathers of the church. It is so in all religions, and forms one of the great incentives of religious life. Our school children are directed to the lives of Washington, Lincoln, and other patriots. The model of the private life of Queen Victoria inspired English social

life for over half-a-century, and its effect still persists. The Swiss have been inspired by the ideal of William Tell. The Japanese national ideal acts in the direction of a positive inspiraton to the young men of that land. Nations like individuals, incline toward their ideals. And this is the "reason" of our advising you to idealize yourself, in a visualized mental image of yourself *as you wish to be.* Hold firmly to your ideal, and you will grow like it—the material manifestation follows upon the mental idealization.

The third phase of this method of Auto-Suggestion consists in "acting out" the part in which you wish to become perfect. Not only do you thus gain the benefit of practice, and repetitive suggestion, in the manner of a rehearsal—but there is also a psychological law involved in this phase. Just as thought tends to take form in action, so does action tend to react upon thought. Let us quote from a few authorities on this subject. Prof. Halleck says: "By restraining the expression of an emotion we can frequently throttle it; by inducing the expression of an emotion we can often cause its allied emotion." Prof. Wm.

James says: "Refuse to express a passion, and it dies. Count ten before venting your anger, and its occasion seems ridiculous. Whistling to keep up courage is no mere figure of speech. On the other hand, sit all day in a moping posture, sigh and reply to everything in a dismal voice, and your melancholy lingers. There is no more valuable precept in moral education than this, as all of us who have experienced know: If we wish to conquer undesirable emotional tendencies in ourselves we must assiduously, and in the first instance cold-bloodedly, *go through the outward movements* of those contrary dispositions which we wish to cultivate. Smooth the brow, brighten the eye, contract the dorsal rather than the ventral aspect of the frame, and speak in a major key, pass the genial compliment, and your heart must indeed be frigid if it does not gradually thaw."

The following quotation from a recent article of Dr. Woods Hutchinson throws light on this question of the reaction of physical states upon mental conditions, moods and character:

"To what extent muscular contractions condition emotions, as Prof. James has sug-

gested, may be easily tested by a quaint and simple little experiment upon a group of the smallest voluntary muscles in the body, those that move the eyeball. Choose some time when you are sitting quietly in your room, free from all disturbing thoughts and influences. Then stand up, and assuming an easy position, cast the eyes upward and hold them in that position for thirty seconds. Instantly and involuntarily you will be conscious of a tendency toward reverential, devotional, contemplative ideas and thoughts. Then turn the eyes sideways, glancing directly to the right or to the left, through half-closed lids. Within thirty seconds images of suspicion, of uneasiness, or of dislike will rise unbidden in the mind. Turn the eyes on one side and slightly downward, and suggestions of jealousy or coquetry will be apt to spring unbidden. Direct your gaze downward toward the floor, and you are likely to go off into a fit of reverie or of abstraction." Bain says: "Most of our emotions are so closely connected with their expression that they hardly exist if the body remains passive." Maudsley says: "The specific muscular action is not merely

an exponent of passion, but truly an essential part of it. If we try while the features are fixed in the expression of one passion to call up in the mind a different one, we shall find it impossible to do so."

In view of the above facts, do you not see why it is important that *action* should be added to saying and seeing, in Auto-Suggestion? Lose no opportunity to act out the part into which you wish to grow. Manifest into action, as frequently as possible, the qualities which you wish to make your own, and in which you wish to develop. Exercise, exercise, exercise; practice, practice, practice; rehearse, rehearse, rehearse! Let your thought manifest and take form in action, for not only do you develop the thought and idea by so doing, but you will also gain the advantage of the reaction of the physical state upon the mental. If you walk down the street with clenched fists, you will soon begin to feel cross and combatitive. If you go about wearing a frown, you will soon experience a feeling of peevishness and irritability, and will manifest it toward those around. Wearing a smile causes the "smile-feeling" to come. It is ac-

tion and reaction, always, between the physical and the mental. Take advantage of this law of life, and turn it to good account in your work of Auto-Suggestion.

In the advice given in the two succeeding chapters, be sure to remember that the *action* and the visualization must always accompany the verbal suggestions recommended to you. Do not be content with suggesting to yourself the qualities you wish to develop, but also visualize them as an ideal, and finally *act them out* in actual life as often as possible. Cultivate the physical characteristics accompanying the mental qualities you wish to develop or acquire. By acting out the qualities in private, you will ascertain just what these physical characteristics are—then practice them until you make them your own, and then acquire the habit of manifesting them permanently. You will be surprised at the benefit of this reflex action, or reaction of the physical upon the mental. This point is often overlooked by the teachers of Auto-Suggestion, but it is most important. We trust that you will give to it the consideration that it merits.

CHAPTER XIX.

CHARACTER BUILDING.

By "Character" we mean the personal qualities and attributes of a man or woman. It is significant that the Greek word from which the word arose signifies an impression as that of a seal or die. Character is really the result of impressions of some kind received by the mind or brain of the person. A person's character is the result of the various impressions that have been made upon it. Character may be moulded, shaped and changed by Auto-Suggestions along the lines mentioned in the preceding chapter—suggestion to oneself; mental imaging; and acting out the part.

In character-building the first thing is to take mental stock of oneself, so as to determine which traits should be inhibited, repressed or restrained and which should be developed. Every one knows his strong and weak points, but few lack the honesty to confess them to themselves. Enter into confes-

sion with yourself, and make a list of the traits which should be restrained, and those which should be developed. Then proceed to develop the desirable ones by the three-fold method; and restrain the undesirable ones by developing their opposites. Let us consider a few of these mental qualities, or characteristics, in order to get some light on the practical working of the method.

1. *Continuity.* This faculty or quality is that which regulates the degree of patient and persistent application to the thing before one. It is the "Stick-to-itive" faculty, which is so deficient in many people. Its cultivation is possible by the following Auto-Suggestion, accompanied by the appropriate mental pictures, and the appropriate action. Auto-Suggestion: "John Smith, you are developing Continuity; you are learning to apply yourself fixedly and firmly to the task before you; you are growing able to concentrate firmly upon one thing until you complete the task; you are growing to give your whole attention to the one thing before you, until it is finished; you are learning to keep up one train of thought until you have exhausted it; you are

finding it easier to do this, and easier to avoid scattering your mental energies—easier each day. You are acquiring a fixed purpose, and a strong concentration. You are growing strong in Continuity. You are developing the brain-centres which manifest Continuity," etc., etc. Accompany this with the mental picture of yourself practicing concentration and persistency, attention and application. Create the ideal of yourself as possessing and manifesting the quality in a high degree. Then endeavor to act out the part as much as possible. Practice with the things before you, and learn to manifest Continuity in your every-day life, allowing no opportunity to escape you. In case you wish to restrain the faculty, should you possess it in too strong a degree, reverse the process and model your method so as to develop the opposite quality—love of variety, diversity, etc.

2. *Combativeness.* This is the faculty of resistance, opposition, etc. Some have it in excess—some are deficient in it. To develop it, use the following Auto-Suggestion: "John Smith, you are learning to stand up for your rights; you are developing the power of right-

ful resistance; you are becoming more spirited and courageous every day; you are growing moral courage; you are sticking to what you believe are your rightful dues; you are standing up against oppression; you are developing the faculty of self-defense; you are learning to refuse to retreat; you are holding your own; you are developing the quality of 'let-me-alone;' you are cultivating the power to stand as firm as a rock against all opposition; you are learning to achieve, conquer, and win out," etc. Accompany this with the appropriate mental pictures, and the appropriate actions. Practice the desired qualities as often as possible. Develop your mental muscle. Stop being a worm of the dust, or human door-mat, and assert your individuality. If you possess this quality in too great a degree, restrain it by cultivating the opposite quality of live-and-let-live; forbearance; brotherly love; etc. The ideal condition is that which lies between the two extremes.

3. *Acquisitiveness.* This is the faculty which manifests in the securing and saving of money and things. Some possess it to an intolerable degree, while others are kept poor

all their lives from a lack of it. To develop this faculty, use the following Auto-Suggestion: "John Smith, you are getting over your foolishness; you are learning to desire money, and to want to save it; you are learning to *get* money and to *hold on* to it; you are developing the ability to get all that is coming to you, and to hold on to it after you get it; you are learning to be frugal and economical, and at the same time are developing the faculty of acquiring the good things of life. You need these things, and you are going to have them—you are beginning to set into operation the things which will bring you these things that you need and want, and you are learning how to hold on to them as they reach you," etc. Accompany this with the mental picture of yourself as "wanting what you want, and wanting it *now*;" of drawing to you from all sides the things you want; as having the things, and holding tight fast to them; see yourself as "having and holding," and as "letting nothing get away from you." Then manifest this thought in action; begin to reach out after the good things of life, *and hold fast to what you get.* Remember the

words of the song: "Every little bit, added to what you've got, makes just a little bit more." Demand your share of the opulence of the world, and get it—then hold on to it. To restrain this quality, develop its opposite—begin to "loosen up," in thought, suggestion and action.

4. *Secretiveness.* This is the faculty of the closed-lips, and silent tongue, and the avoidance of telling one's affairs to the world. A certain amount of it is very desirable, for many reasons; an excess of it tends toward untruthfulness and deception. To develop, use the following Auto-Suggestion: "John Smith, you are learning to keep your own secrets; you are learning the art of keeping your mouth closed and your tongue quiet; you are learning that "a closed mouth catches no flies," and are acting accordingly; you are developing the faculty of holding your tongue, and to avoid "blabbing" your secrets to the world; you are becoming reticent and self-contained; you are avoiding wearing your heart on your sleeve, or of exhibiting your open wounds that the world may stick its finger into them; you are learning to "lay

low, and keep dark;" you are learning to "saw wood and say nothing;" you are learning to set the watch-dog of your caution at the door of your mind, so as to prevent others from entering; you are developing the quality of being guarded and wary; you are becoming reserved and cautious; you are avoiding the role of the fool who tells all he knows, for the secret amusement and benefit of others; you are avoiding all gushing and emotional slushiness; you are learning to dwell within your own mental castle, and gazing through your windows at the world, without inviting them to occupy the inner chambers of your soul. You are inside your own castle, and have locked the door," etc. Accompany this with the appropriate ideal and mental picture, and *make good in action. Be* secretive, as well as saying you are. Let your thought take form in action.

The above should give you an idea of the method to be applied in the development of any faculty. Apply the same method in developing the other faculties mentioned below, and any others that may seem desirable to you. There is no secret in the words. Model

your Auto-Suggestion in accordance with the characteristics of each faculty as given below, and you can make your own Auto-Suggestions.

5. *Approbativeness.* This is the faculty which causes us to feel hurt when we are condemned by others; and to feel exalted when others flatter or "jolly" us. The majority of us have too much of this quality, and restraint, rather than development is necessary in most cases. The best way to restrain this faculty is to cultivate the spirit of Individuality and true Self-Esteem. Learn to feel: "They say; what do they say; let them say!" Learn to stand on your own feet, and smile at the world. Learn to say "I Am," and feel that you are surrounded with a protective atmosphere of individual strength, through which the adverse criticism cannot reach you. At the same time, learn to be proof against flattery and the false praise of others. Learn to value your own satisfaction as more than the praise of the world. Learn to live in spite of condemnation or adverse criticism; and without the flattery of knaves, fools, and self-seeking people.

6. *Self-Esteem.* True Self-Esteem consists in the feeling of Individuality, as distinct from Personality. Personality is the phase of the self which is affected by criticism or flattery—its organ is Approbativeness. The true individual feels that he is *real*—that he is a centre of the cosmic energy—that he is standing on his own feet, and is a necessary part of the world's being. Self-Esteem does not display Egotism, for that fault belongs to the personality. Self-Esteem is Egoistic but not Egotistic—there is a world of difference between these terms. Cultivate the "I Am" quality within yourself—develop the individuality. "I Am an Individual" is the key note of true Self-Esteem.

7. *Firmness.* This is the faculty of steadfastness, stability, perseverance, decision, tenacity, will. It may be cultivated by the methods given above. The qualities of firmness, its ideal, its actions, are too well known to require a recital.

Hope—the faculty of optimism, expectation of good, bright outlook, etc.; Constructiveness, the faculty of "making things"—the inventive faculty; and many other positive

qualities, may be cultivated by the methods already given. In suggesting these qualities to yourself, use the same words and terms that you would use were you suggesting to another person. By keeping this rule in mind, you should have no trouble in selecting the appropriate suggestions.

The qualities and faculties given above are for the most part what are known as The Positive Qualities, and are those in which the majority of people are deficient. For this reason we have placed special emphasis upon them. There are other valuable qualities, necessary in a well-rounded character, but we have thought it best to emphasize these Positive Qualities for the reason that the lack of development of them has resulted in so many weak characters, and that the work should be directed to the point of the greatest need. In conclusion, we ask you to consider these words used by us in concluding a previous work, in which the spirit of the Positive Qualities is brought out: "I have tried to infuse my words with the strong, vital energy, which I feel surging through me as I write out this message of strength to you. I trust that these words will act as a current

of verbal electrons, each carrying its full charge of dynamic power. And I trust that each word will serve to fill you with the mind-power that gave them birth, and will thus awaken in you a similar mental state, desire and will, to be strong, forceful and dynamic—determined to assert your individuality in being and doing that which the universal creative desire and will is hoping that you will be and do. I send to you this message, charged with the very dynamic vibrations of my brain, as it transforms and converts the mind-power into thoughts and words. I send it to you—yes, *you*, who are now reading the words—with all the energy, force and power at my command, to the end that it pierce your armor of indifference, fear and doubt, and 'I Can't.' And that reaching your heart of desire, it may fill you with the very spirit of individuality, conscious egohood, perception of reality, and realization of the 'I.' So that from now on your battle cry will be changed, and you will plunge into the thick of the fight, filled with the Berserker rage, like the Icelandic hero of old, and shouting your positive cry of freedom: 'I Can and I Will!' you will mow

your way clear through the ranks of the hordes of ignorance, and negativity, and reach the heights beyond. This is my message to *you*—the Individual!"

CHAPTER XX.

HEALTH, HAPPINESS AND PROSPERITY.

In the words used as the title for this concluding chapter—Health, Happiness and Prosperity—are summed up the majority of the things which render life worth living, and for which mankind is striving. And if Auto-Suggestion tends to develop these qualities or states, then it plays a most important part in the life of mankind. And all students of the subject are forced to concede that Auto-Suggestion has much to do with Health, Happiness and Prosperity, either in the direction of producing them, or of preventing them. Let us give a brief final consideration to the subject of Auto-Suggestion in its effect of the Health, Happiness and Prosperity of men and women.

In the first place, we have seen the therapeutic value of Suggestion, in its various phases. And we have seen that each and every effect of Therapeutic Suggestion really has Auto-Suggestion as its fundamental prin-

ciple, for, at the last, the healing power of Suggestion is found to reside in the mind of the individual, himself, and that all of its activities arise from the calling into effect of the mental power of the person by Auto-Suggestion, conscious or unconscious. And every form of Therapeutic Suggestion mentioned in this book as employed by the various practitioners, may be applied by the person himself, to himself, by Auto-Suggestion. We have explained how one may suggest to himself, with the same effect as if he were suggesting to another. In this way the whole system of Suggestive Therapeutics is open to each and every person, without the aid of a healer or practitioner, if he has the perseverance and will to so apply it.

Moreover, the careful reader of this book will have seen that one's health depends materially upon the character of his mental states—that the mind exerts a tremendous influence over the physical states. He will have seen that the influence of Fear, Worry, Anger and gloomy mental states are actually depressing in their effects upon the functions of the bodily organs. And that Hope, Faith,

Courage and Cheerfulness exert a positive, invigorating effect upon the physical functions. This being the case, does it not follow that a habit of proper Auto-Suggestion once acquired and practiced, the person must of necessity interpose a resistance to disease, and develop a normal, healthy condition of physical life. Read over carefully what we have said in the part of this book devoted to Therapeutic Suggestion, and then apply the principles along the lines of Auto-Suggestion. Proper Auto-Suggestion comes as near to being a universal remedy for disease, as anything ever known to man. That is, Auto-Suggestion accompanied by the proper ideals and mental pictures, and the manifestation in action, as described in this book. If you *suggest* Health to yourself; *think* Health; *see* Health; and *act* Health—you will *manifest* Health. *Let your ideal, model and pattern always be the Healthy Man or Woman, and then model all your suggestions, thoughts and actions accordingly.*

As for Happiness, much depends upon the possession of Health. And the first step in the acquisition of Happiness is the develop-

ment of Health. But, in addition to this the Mental Attitude of persons depend very materially upon the principle of Auto-Suggestion and the will. By steadily refusing to allow the entrance of depressing negative thoughts, and the constant seeking for the positive, invigorating thoughts, you have the key of the proper Mental Attitude. "As a man thinketh, so is he." Man grows to resemble that upon which he fixes his thoughts. A determination to see and think of only the positive bright things of life, and the refusal to admit or consider the negative, depressing things of life, will produce a habitual mental attitude which will make for Happiness. There are both bright and dark things in life, but we have the right to turn our attention to which ever set of facts and things we desire. We may prefer to see only the unpleasant side and many seemingly so prefer; or we may prefer to see only the bright side. It is all a matter of determination and will, along the lines of using the attention. The attention finds that which it seeks, good or bad. There are always two sides to everything—you have the right to choose which side you will gaze

upon. Optimism and Pessimism are but the two sides of the Shield of Life—take your choice. Much depends upon the Mental Attitude, and the Mental Attitude depends largely upon Auto-Suggestion, in its fullest sense.

Happiness is not so much a matter of outside things as is generally imagined. You have seen many persons surrounded by all that wealth, position, or influence could procure—and still they are unhappy. On the contrary, you have seen many people like "Mrs Wiggs of the Cabbage Patch," or like "Glad" in "The Dawn of a Tomorrow," who manage to extract Happiness from the must unpromising surroundings. Happiness comes from *within*. If you are not able to extract it from within your soul, you will never get it from without. It is something that belongs to the inner nature of people—it exists nowhere else. No one ever obtained perfect happiness from outside things, people, or conditions—but many have found it dwelling within themselves. And, so, if you cultivate your "within" you have found the secret of happiness. And the "within" may be developed and cultivated by Auto-Suggestion, as

we have defined the word. You live in your mind, after all—therefore you should make your mental dwelling-place fit to live in.

Prosperity depends upon a number of things, not the least of which is the inner mental attitude and condition of those seeking it. The possession of certain qualities of mind is generally regarded as necessary for Success; and the possession of opposite qualities are generally regarded as destructive to Success. If ones mental faculties or qualities were fixed and unalterable, then one might despair of attaining Success, in the majority of cases. But The New Psychology has shown us how we may develop desirable qualities, and restrain undesirable ones, by Auto-Suggestion. So we see that even in this field, Auto-Suggestion plays an important part.

All improvement comes by education in some form. Auto-Suggestion is simply a form of education and training. The fact that you are both teacher and student, does not alter the question. A recognition of the existence of the subconscious mind explains the dual-action in Auto-Suggestion. One has it within his own power *to make of himself what he will,*

providing he will devote to the task energy, determination and persistency. And even these qualities may be developed and encouraged, if one be deficient in them.

There is a "Something Within" each person that is the King and Master of all the remaining portions of his being. Call this "something within" the soul, the will, the ego, or what not, the fact remains that this part of the self is Sovereign and Dominant. In the measure that this Sovereign manifests its power, so is the degree of Individuality. The majority of people do not realize that they have this Sovereign Self within them, and so yield themselves without resistance to environment and outward influences. In Auto-Suggestion, particularly when one acquires the "knack" of it, there is manifested the phenomenon of this Sovereign Self mounting its mental throne and asserting its right and might to govern. Then does man become the master of himself, instead of being a slave to circumstance and environment, or the influence of others. In the realization, recognition and manifestation of this "I Am" within us, lies the secret of Health, Happiness

and Prosperity. As Chas. F. Lummis has said: "Man was meant to be, and ought to be, stronger and more than anything that can happen to him. Circumstances, 'fate,' 'luck' are all outside, and if he cannot always change them, *he can always beat them.* . . . I am all right. I am bigger than anything that can happen to me. All these things are outside my door, *and I've got the key.*" And so say all who have found the "something within," and have gained the Mastery of Self by Self!

HOW TO PRACTICE CONSCIOUS AUTOSUGGESTION

Every morning before getting up and every evening as soon as you are in bed, shut your eyes, and repeat twenty times in succession, *moving your lips* (this is indispensable), and counting *mechanically* on a long string with twenty knots, the following phrase: *"Day by day, in every way I am getting better and better"*. Do not think of anything particular, as the words *"in every way"* apply to everything.

Make this autosuggestion with confidence, with faith, with the certainty of obtaining what you want. The greater the conviction, the greater and the more rapid will be the results obtained.

Further, every time in the course of the day or night that you feel any distress physical or mental, immediately *affirm to yourself* that you will not consciously contribute to it, and that you are going to make it disappear; then isolate yourself as much as possible, shut your eyes, and passing your hand over your forehead, if it is something mental, or over the part which is painful, if it is something physical, repeat *extremely quickly*, moving your lips, the words: "It is going, it is going—", etc., etc., as long as it may be necessary. With a little practice the physical or mental distress will have vanished in 20 to 25 seconds. Begin again whenever it is necessary. Avoid carefully any effort in practising autosuggestion.

EMILE COUÉ

The Master Mind of Autosuggestion

SELF MASTERY
THROUGH
CONSCIOUS AUTOSUGGESTION

Suggestion, or rather Autosuggestion, is quite a new subject, and yet at the same time it is as old as the world. It is new in the sense that until now it has been wrongly studied and in consequence wrongly understood; it is old because it dates from the appearance of man on the earth. In fact autosuggestion is an instrument that we possess at birth, and in this instrument, or rather in this force, resides a marvelous and incalculable power, which according to circumstances produces the best or the worst results. Knowledge of this force is useful to each one of us, but it is peculiarly indispensable to doctors, magistrates, lawyers, and to those engaged in the work of education.

By knowing how to practise it *consciously* it is possible in the first place to avoid provoking in others bad autosuggestions which may have disastrous consequences, and secondly, *consciously* to provoke good ones instead, thus bringing physical health to the sick, and moral health to the neurotic and the erring, the unconscious victims of anterior autosuggestions, and to guide into the right path those who had a tendency to take the wrong one.

THE CONSCIOUS SELF AND THE UNCONSCIOUS SELF

In order to understand properly the phenomena of suggestion, or to speak more correctly of autosuggestion, it is necessary to know that two absolutely distinct selves exist within us. Both are intelligent, but while one is conscious the other is unconscious. For this reason the ex-

istence of the latter generally escapes notice. It is however easy to prove its existence if one merely takes the trouble to examine certain phenomena and to reflect a few moments upon them. Let us take for instance the following examples:

Every one has heard of somnambulism; every one knows that a somnambulist gets up at night *without waking,* leaves his room after either dressing himself or not, goes downstairs, walks along corridors, and after having executed certain acts or accomplished certain work, returns to his room, goes to bed again, and shows next day the greatest astonishment at finding work finished which he had left unfinished the day before.

It is however he himself who has done it without being aware of it. What force has his body obeyed if it is not an unconscious force, in fact his unconscious self?

Let us now examine the alas, too frequent case of a drunkard attacked by *delirium tremens.* As though seized with madness he picks up the nearest weapon, knife, hammer, or hatchet, as the case may be, and strikes furiously those who are unlucky enough to be in his vicinity. Once the attack is over, he recovers his senses and contemplates with horror the scene of carnage around him, without realizing that he himself is the author of it. Here again is it not the unconscious self which has caused the unhappy man to act in this way?*

If we compare the conscious with the unconscious self we see that the conscious self is often possessed of a very unreliable memory while the unconscious self on the contrary is provided with a marvellous and impeccable memory which registers without our knowledge the smallest events, the least important acts of our existence. Further, it is credulous and accepts with unreasoning docility what

* And what aversions, what ills we create for ourselves, everyone of us and in every domain by not "immediately" bringing into play "good conscious autosuggestions" against our "bad unconscious autosuggestions," thus bringing about the disappearance of all unjust suffering.

t is told. Thus, as it is the unconscious that is responsible for the functioning of all our organs by the intermediary of the brain, a result is produced which may seem rather paradoxical to you: that is, if it believes that a certain organ functions well or ill or that we feel such and such an impression, the organ in question does indeed function well or ill, or we do feel that impression.

Not only does the unconscious self preside over the functions of our organism, but also over *all our actions whatever they are.* It is this that we call imagination, and it is this which, contrary to accepted opinion, *always* makes us act even, and *above all,* against *our will* when there is antagonism between these two forces.

WILL AND IMAGINATION

If we open a dictionary and look up the word "will", we find this definition: "The faculty of freely determining certain acts". We accept this definition as true and unattackable, although nothing could be more false. This will that we claim so proudly, always *yields* to the imagination. It is an *absolute* rule that admits of no *exception.*

Blasphemy! Paradox! you will exclaim. Not at all! On the contrary, it is the purest truth, I shall reply.

In order to convince yourself of it, open your eyes, look round you and try to understand what you see. You will then come to the conclusion that what I tell you is not an idle theory, offspring of a sick brain but the simple expression of a *fact.*

Suppose that we place on the ground a plank 30 feet long by 1 foot wide. It is evident that everybody will be capable of going from one end to the other of this plank without stepping over the edge. But now change the conditions of the experiment, and imagine this plank placed at the height of the towers of a cathedral. Who then will be capable of advancing even a few feet along this narrow path? Could you hear me speak? Probably not. Before you had taken two steps you would begin to tremble, and

in spite of every effort of your will you would be certain to fall to the ground.

Why is it then that you would not fall if the plank is on the ground, and why should you fall if it is raised to a height above the ground? Simply because in the first case you *imagine* that it is easy to go to the end of this plank, while in the second case you imagine that you *cannot* do so.

Notice that your *will* is powerless to make you advance; if you *imagine* that you *cannot,* it is *absolutely* impossible for you to do so. If tilers and carpenters are able to accomplish this feat, it is because they think they can do it.

Vertigo is entirely caused by the picture we make in our minds that we are going to fall. This picture transforms itself immediately into fact *in spite of all the efforts of our will,* and the more violent these efforts are, the quicker is the opposite to the desired result brought about.

Let us now consider the case of a person suffering from insomnia. If he does not make any effort to sleep, he will lie quietly in bed. If on the contrary he tries to force himself to sleep by his *will,* the more efforts he makes, the more restless he becomes.

Have you not noticed that the more you try to remember the name of a person which you have forgotten, the more it eludes you, until, substituting in your mind the idea "I shall remember in a minute" to the idea "I have forgotten", the name comes back to you of its own accord without the least effort?

Let those of you who are cyclists remember the days when you were learning to ride. You went along clutching the handle bars and frightened of falling. Suddenly catching sight of the smallest obstacle in the road you tried to avoid it, and the more efforts you made to do so, the more surely you rushed upon it.

Who has not suffered from an attack of uncontrollable laughter, which bursts out more violently the more one tries to control it?

What was the state of mind of each person in these different circumstances? "I *do not want* to fall but I *cannot*

help doing so"; *"I want* to sleep but I *cannot"; I want* to remember the name of Mrs. So and So, but I *cannot"; "I want* to avoid the obstacle, but I *cannot"; I want* to stop laughing, but I *cannot"*.

As you see, in each of these conflicts it is always the *imagination* which gains the victory over the *will,* without any exception.

To the same order of ideas belongs the case of the leader who rushes forward at the head of his troops and always carries them along with him, while the cry "Each man for himself!" is almost certain to cause a defeat. Why is this? It is because in the first case the men *imagine* that they must go *forward,* and in the second they *imagine* that they are conquered and must fly for their lives.

Panurge was quite aware of the contagion of example, that is to say the action of the imagination, when, to avenge himself upon a merchant on board the same boat, he bought his biggest sheep and threw it into the sea, certain beforehand that the entire flock would follow, which indeed happened.

We human beings have a certain resemblance to sheep, and involuntarily, we are irresistibly impelled to follow other people's examples, *imagining* that we cannot do otherwise.

I could quote a thousand other examples but I should fear to bore you by such an enumeration. I cannot however pass by in silence this fact which shows the enormous power of the imagination, or in other words of the unconscious in its struggle aganst the *will.*

There are certain drunkards who wish to give up drinking, but who cannot do so. Ask them, and they will reply in all sincerity that they desire to be sober, that drink disgusts them, but that they are irresistibly impelled to drink against their *will,* in spite of the harm they know it will do them.

In the same way certain criminals commit crimes *in spite of themselves,* and when they are asked why they acted so,

they answer "I could not help it, something impelled me, it was stronger than I."

And the drunkard and the criminal speak the truth; they are forced to do what they do, for the simple reason they imagine they cannot prevent themselves from doing so.

Thus we who are so proud of our will, who believe that we are free to act as we like, are in reality nothing but wretched puppets of which our imagination holds all the strings. We only cease to be puppets when we have learned to guide our imagination.

SUGGESTION AND AUTOSUGGESTION

According to the preceding remarks we can compare the imagination to a torrent which fatally sweeps away the poor wretch who has fallen into it, in spite of his efforts to gain the bank. This torrent seems indomitable; but if you know how, you can turn it from its course and conduct it to the factory, and there you can transform its force into movement, heat, and electricity.

If this simile is not enough, we may compare the imagination—"the madman at home" as it has been called—to an unbroken horse which has neither bridle nor reins. What can the rider do except let himself go wherever the horse wishes to take him? And often if the latter runs away, his mad career only comes to end in the ditch. If however the rider succeeds in putting a bridle on the horse, the parts are reversed. It is no longer the horse who goes where he likes, it is the rider who obliges the horse to take him wherever he wishes to go.

Now that we have learned to realize the enormous power of the unconscious or imaginative being, I am going to show how this self, hitherto considered indomitable, can be as easily controlled as a torrent or an unbroken horse. But before going any further it is necessary to define carefully two words that are often used without being properly understood. These are the words *suggestion* and *autosuggestion.*

What then is suggestion? It may be defined as "the act of imposing an idea on the brain of another". Does this action really exist? Properly speaking, no. Suggestion does not indeed exist by itself. It does not and cannot exist except on the *sine qua non* condition of transforming itself into *autosuggestion* in the subject. This latter word may be defined as "the implanting of an idea in oneself by oneself."

You may make a suggestion to someone; if the unconscious of the latter does not accept the suggestion, if it has not, as it were, digested it, in order to transform it into *autosuggestion,* it produces no result. I have myself occasionally made a more or less commonplace suggestion to ordinarily very obedient subjects quite unsuccessfully. The reason is that the unconscious of the subject refused to accept it and did not transform it into *autosuggestion.*

THE USE OF AUTOSUGGESTION

Let us now return to the point where I said that we can control and lead our imagination, just as a torrent or an unbroken horse can be controlled. To do so, it is enough in the first place to know that this is possible (of which fact almost everyone is ignorant) and secondly, to know by what means it can be done. Well, the means is very simple; it is that which we have used every day since we came into the world, without wishing or knowing it and absolutely unconsciously, but which unfortunately for us, we often use wrongly and to our own detriment. This means is *autosuggestion.*

Whereas we constantly give ourselves unconscious autosuggestions, all we have to do is to give ourselves conscious ones, and the process consists in this: first, to weigh carefully in one's mind the things which are to be the object of the autosuggestion, and according as they require the answer "yes" or "no", to repeat several times without thinking of anything else: "This thing is coming", or "this thing is going away"; "this thing will, or will not

happen, etc., etc. . . .".* If the unconscious accepts this suggestion and transforms it into an autosuggestion, the thing or things are realized in every particular.

Thus understood, *autosuggestion* is nothing but hypnotism as I see it, and I would define it in these simple words: *The influence of the imagination upon the moral and physical being of mankind.* Now this influence is undeniable, and without returning to previous examples, I will quote a few others.

If you persuade yourself that you can do a certain thing, provided this thing be *possible*, you will do it however difficult it may be. If on the contrary you *imagine* that you cannot do the simplest thing in the world, it is impossible for you to do it, and molehills become for you unscalable mountains.

Such is the case of neurasthenics, who, believing themselves incapable of the least effort, often find it impossible even to walk a few steps without being exhausted. And these same neurasthenics sink more deeply into their depression, the more efforts they make to throw it off, like the poor wretch in the quicksands who sinks in all the deeper the more he tries to struggle out.

In the same way it is sufficient to think a pain is going, to feel it indeed disappear little by little, and inversely, it is enough to think that one suffers in order to feel the pain begin to come immediately.

I know certain people who predict in advance that they will have a sick headache on a certain day, in certain circumstances, and on that day, in the given circumstances, sure enough, they feel it. They brought their illness on themselves, just as others cure theirs by *conscious autosuggestion.*

I know that one generally passes for mad in the eyes of the world if one dares to put forward ideas which it is not accustomed to bear. Well, at the risk of being thought so, I say that if certain people are ill mentally and physically,

* Of course, the thing must be in our power.

it is that they *imagine* themselves to be ill mentally or physically. If certain others are paralytic without having any lesion to account for it, it is that they imagine themselves to be paralyzed, and it is among such persons that the most extraordinary cures are produced. If others again are happy or unhappy, it is that they *imagine* themselves to be so, for it is possible for two people in exactly the same circumstances to be, the one *perfectly happy,* the other *absolutely wretched.*

Neurasthenia, stammering, aversions, kleptomania, certain cases of paralysis, are nothing but the result of unconscious autosuggestion, that is to say the result of the action of the *unconscious* upon the physical and moral being.

But if our unconscious is the source of many of our ills, it can also bring about the cure of our physical and mental ailments. It can not only repair the ill it has done, but cure real illnesses, so strong is its action upon our organism.

Shut yourself up alone in a room, seat yourself in an armchair, close your eyes to avoid any distraction, and concentrate your mind for a few moments on thinking: "Such and such a thing is going to disappear", or "Such and such a thing is coming to pass".

If you have really made the autosuggestion, that is to say, if your unconscious has assimilated the idea that you have presented to it, you are astonished to see the thing you have thought come to pass. (Note that it is the property of ideas autosuggested to exist within us unrecognized; and we can only know of their existence by the effect they produce.) But above all, and this is an essential point, the **will must not be brought into play in practising autosuggestion;** for, if it is not in agreement with the imagination, if one thinks: "I will make such and such a thing happen", and the imagination says: "You are willing it, but it is not going to be", not only does one not obtain what one wants, but even exactly the reverse is brought about.

This remark is of **capital** importance, and explains why results are so unsatisfactory when, in treating moral ailments, one strives to *re-educate the will.* It is the *training of the imagination* which is necessary, and it is thanks to this shade of difference that my method has often succeeded where others—and those not the least considered—have failed. From the numerous experiments that I have made daily for twenty years, and which I have examined with minute care, I have been able to deduct the following conclusions which I have summed up as laws:

1. When the will and the imagination are antagonistic, it is always the imagination which wins, *without any exception.*

2. In the conflict between the will and the imagination, the force of the imagination is in *direct ratio to the square of the will.*

3. When the will and the imagination are in agreement, one does not add to the other, but one is multiplied by the other.

4. The imagination can be directed.

(The expressions "In direct ratio to the square of the will" and "Is multiplied by" are not rigorously exact. They are simply illustrations destined to make my meaning clearer.)

After what has just been said it would seem that nobody ought to be ill. That is quite true. Every illness, whatever it may be, *can* yield to *autosuggestion,* daring and unlikely as my statement may seem; I do not say *does always yield,* but *can yield,* which is a different thing.

But in order to lead people to practise conscious autosuggestion they must be taught how, just as they are taught to read or write or play the piano.

Autosuggestion is, as I said above, an instrument that we possess at birth, and with which we play unconsciously all our life, as a baby plays with its rattle. It is however a dangerous instrument; it can wound or even kill you if you handle it imprudently and unconsciously. It can on the contrary save your life when you know how to employ

it *consciously.* One can say of it as Æsop said of the tongue: "It is at the same time the best and the worst thing in the world".

I am now going to show you how everyone can profit by the beneficient action of *autosuggestion* consciously applied. In saying "every one", I exaggerate a little, for there are two classes of persons in whom it is difficult to arouse conscious autosuggestion:

1. The mentally undeveloped who are not capable of understanding what you say to them.
2. *Those who are unwilling to understand.*

HOW TO TEACH PATIENTS TO MAKE AUTOSUGGESTIONS

The principle of the method may be summed up in these few words: *It is impossible to think of two things at once,* that is to say that two ideas may be in juxtaposition, but they cannot be superimposed in our mind.

Every thought entirely filling our mind becomes true for us and tends to transform itself into action.

Thus if you can make a sick person think that her trouble is getting better, it will disappear; if you succeed in making a kleptomaniac think that he will not steal any more, he will cease to steal, etc., etc.

This training which perhaps seems to you an impossibility, is, however, the simplest thing in the world. It is enough, by a series of appropriate and graduated experiments, to teach the subject, as it were the A. B. C. of conscious thought, and here is the series: by following it to the letter one can be absolutely sure of obtaining a good result, except with the two categories of persons mentioned above.

First experiment. * *Preparatory.*—Ask the subject to

* These experiments are those of Sage of Rochester.

stand upright, with the body as stiff as an iron bar, the feet close together from toe to heel, while keeping the ankles flexible as if they were hinges. Tell him to make himself like a plank with hinges at its base, which is balanced on the ground. Make him notice that if one pushes the plank slightly either way it falls as a mass without any resistance, in the direction in which it is pushed. Tell him that you are going to pull him back by the shoulders and that he must let himself fall in your arms without the slightest resistance, turning on his ankles as on hinges, that is to say keeping the feet fixed to the ground. Then pull him back by the shoulders and if the experiment does not succeed, repeat it until it does, or nearly so.

Second experiment.—Begin by explaining to the subject that in order to demonstrate the action of the imagination upon us, you are going to ask him in a moment to think: "I am falling backwards, I am falling backwards . . ." Tell him that he must have no thought but this in his mind, that he must not reflect or wonder if he is going to fall or not, or think that if he falls he may hurt himself, etc., or fall back purposely to please you, but that if he really feels something impelling him to fall backwards, he must not resist but obey the impulse.

Then ask your subject to raise the head high and to shut his eyes, and place your right fist on the back of his neck, and your left hand on his forehead, and say to him: "Now think: I am falling backwards, I am falling backwards, etc., etc. . . " and, indeed, "You are falling backwards, You . . . are . . . fall . . . ing . . . back . . . wards, etc." At the same time slide the left hand lightly backwards to the left temple, above the ear, and remove very slowly but with a continuous movement the right fist.

The subject is immediately felt to make a slight movement backwards, and either to stop himself from falling or else to fall completely. In the first case, tell him that he has resisted, and that he did not think just that he was falling, but that he might hurt himself if he did fall. That is true, for if he had not thought the latter, he would have

fallen like a block. Repeat the experiment using a tone of command as if you would force the subject to obey you. Go on with it until it is completely successful or very nearly so. The operator should stand a little behind the subject, the left leg forward and the right leg well behind him, so as not to be knocked over by the subject when he falls. Neglect of this precaution might result in a double fall if the person is heavy.

Third experiment.—Place the subject facing you, the body still stiff, the ankles flexible, and the feet joined and parallel. Put your two hands on his temples without any pressure, look fixedly, without moving the eyelids, at the root of his nose, and tell him to think: "I am falling forward, I am falling forward . . . " and repeat to him, stressing the syllables, "You are fall . . . ing for . . . ward, You are fall . . . ing . . . for . . . ward . . ." without ceasing to look fixedly at him.

Fourth experiment.—Ask the subject to clasp his hands as tight as posible, that is to say, until the fingers tremble slightly, look at him in the same way as in the preceding experiment and keep your hands on his as though to squeeze them together still more tightly. Tell him to think that he cannot unclasp his fingers, that you are going to count three, and that when you say "three" he is to try to separate his hands while thinking all the time: "I cannot do it, I cannot do it . . . " and he will find it impossible. Then count very slowly, "one, two, three", and add immediately, detaching the syllables: "You . . . can . . . not . . . do it . . . You can . . . not . . . do . . . it . . " If the subject is thinking properly, "I cannot do it", not only is he unable to separate his fingers, but the latter clasp themselves all the more tightly together the more efforts he makes to separate them. He obtains in fact exactly the contrary to what he wants. In a few moments say to him: Now think: "I can do it", and his fingers will separate themselves.

Be careful always to keep your eyes fixed on the root of the subject's nose, and do not allow him to turn his eyes

away from yours for a single moment. If he is able to unclasp his hands, do not think it is your own fault, it is the subject's, he has not properly thought: "I cannot". Assure him firmly of this, and begin the experiment again.

Always use a tone of command which suffers no disobediance. I do not mean that it is necessary to raise your voice; on the contrary it is preferable to employ the ordinary pitch, but stress every word in a dry and imperative tone.

When these experiments have been successful, all the others succeed equally well and can be easily obtained by carrying out to the letter the instructions given above.

Some subjects are very sensitive, and it is easy to recognize them by the fact that the contraction of their fingers and limbs is easily produced. After two or three successful experiments, it is no longer necessary to say to them: "Think this", or "think that"; You need only, for example, say to them simply—but in the imperative tone employed by all good suggestionists—"Close your hands; now you cannot open them". "Shut your eyes; now you cannot open them", and the subject finds it absolutely impossible to open the hands or the eyes in spite of all his efforts. Tell him in a few moments: "You can do it now", and the de-contraction takes place instantaneously.

These experiments can be varied to infinity. Here are a few more: Make the subject join his hands, and suggest that they are welded together; make him put his hand on the table, and suggest that it is stuck to it; tell him that he is fixed to his chair and cannot rise; make him rise, and tell him he cannot walk; put a penholder on the table and tell him that it weighs a hundredweight, and that he cannot lift it, etc., etc.

In all these experiments, I cannot repeat too often, it is not *suggestion* properly so-called which produces the phenomena, but the *autosuggestion* which is consecutive to the suggestion of the operator.

METHOD OF PROCEDURE IN CURATIVE SUGGESTION

When the subject has passed through the preceding experiments and has understood them, he is ripe for curative suggestion. He is like a cultivated field in which the seed can germinate and develop, whereas before it was but rough earth in which it would have perished.

Whatever ailment the subject suffers from, whether it is physical or mental, it is important to proceed always in the same way, and to use the same words with a few variations according to the case.

Say to the subject: "Sit down and close your eyes. I am not going to try and put you to sleep as it is quite unnecessary. I ask you to close your eyes simply in order that your attention may not be distracted by the objects around you. Now tell yourself that every word I say is going to fix itself in your mind, and be printed, engraved, and encrusted in it, that, there, it is going to stay fixed, imprinted, and encrusted, and that without your will or knowledge, in fact perfectly unconsciously on your part, you yourself and your whole organism are going to obey. In the first place I say that every day, three times a day, in the morning, at midday, and in the evening, at the usual meal times, you will feel hungry, that is to say, you will experience the agreeable sensation which makes you think and say: "Oh! how nice it will be to have something to eat!" You will then eat and enjoy your food, without of course overeating. You will also be careful to masticate it properly so as to transform it into a sort of soft paste before swallowing it. In these conditions you will digest it properly, and so feel no discomfort, inconvenience, or pain of any kind either in the stomach or intestines. You will assimilate what you eat and your organism will make use of it to make blood, muscle, strength and energy, in a word: Life.

Since you will have digested your food properly, the function of excretion will be normal, and every morning,

on rising, you will feel the need of evacuating the bowels, and without ever being obliged to take medicine or to use any artifice, you will obtain a normal and satisfactory result.

Further, every night from the time you wish to go to sleep till the time you wish to wake next morning, you will sleep deeply, calmly, and quietly, without nightmares, and on waking you will feel perfectly well, cheerful, and active.

Likewise, if you occasionally suffer from depression, if you are gloomy and prone to worry and look on the dark side of things, from now onwards you will cease to do so, and, instead of worrying and being depressed and looking on the dark side of things, you are going to feel perfectly cheerful, possibly without any special reason for it, just as you used to feel depressed for no particular reason. I say further still, that even if you have real reason to be worried and depressed you are not going to be so.

If you are also subject to occasional fits of impatience or ill-temper you will cease to have them: on the contrary you will be always patient and master of yourself, and the things which worried, annoyed, or irritated you, will henceforth leave you absolutely indifferent and perfectly calm.

If you are sometimes attacked, pursued, haunted, by bad and unwholesome ideas, by apprehensions, fears, aversions, temptations, or grudges against other people, all that will be gradually lost sight of by your imagination, and will melt away and lose itself as though in a distant cloud where it will finally disappear completely. As a dream vanishes when we wake, so will all these vain images disappear.

To this I add that all your organs are performing their functions properly. The heart beats in a normal way and the circulation of the blood takes place as it should; the lungs are carrying out their functions, as also the stomach, the intestines, the liver, the biliary duct, the kidneys and the bladder. If at the present moment any of them is act-

ing abnormally, that abnormality is becoming less every day, so that quite soon it will have vanished completely, and the organ will have recovered its normal function. Further, if there should be any lesions in any of these organs, they will get better from day to day and will soon be entirely healed. (With regard to this, I may say that it is not necessary to know which organ is affected for it to be cured. Under the influence of the autosuggestion "Every day, in every respect, I am getting better and better", the unconscious acts upon the organ which it can pick out itself.)

I must also add—and it is extremely important—that if up to the present you have lacked confidence in yourself, I tell you that this self-distrust will disappear little by little and give place to self-confidence, based on the knowledge of this force of incalculable power which is in each one of us. It is absolutely necessary for every human being to have this confidence. Without it one can accomplish nothing, with it one can accomplish whatever one likes, (*within reason,* of course). You are then going to have confidence in yourself, and this confidence gives you the assurance that you are capable of accomplishing perfectly well whatever you wish to do,—*on condition that it is reasonable,*—and whatever it is your duty to do.

So when you wish to do something reasonable, or when you have a duty to perform, always think that it is *easy,* and make the words *difficult, impossible, I cannot, it is stronger than I, I cannot prevent myself from...,* disappear from your vocabulary; they are not English. What is English is: *"It is easy and I can".* By considering the thing easy it becomes so for you, although it might seem difficult to others. You will do it quickly and well, and without fatigue, because you do it without effort, whereas if you had considered it as difficult or impossible it would have become so for you, simply because you would have thought it so.

To these general suggestions which will perhaps seem

long and even childish to some of you, but which are necessary, must be added those which apply to the particular case of the patient you are dealing with.

All these suggestions must be made in a monotonous and soothing voice (always emphasizing the essential words), which although it does not actually send the subject to sleep, at least makes him feel drowsy, and think of nothing in particular.

When you have come to the end of the series of suggestions you address the subject in these terms: "In short, I mean that from every point of view, physical as well as mental, you are going to enjoy excellent health, better health than that you have been able to enjoy up to the present. Now I am going to count three, and when I say "Three", you will open your eyes and come out of the passive state in which you are now. You will come out of it quite naturally, without feeling in the least drowsy or tired, on the contrary, you will feel strong, vigorous, alert, active, full of life; further still, you will feel very cheerful and fit in every way. "ONE—TWO—THREE—" At the word "three" the subject opens his eyes, always with a smile and an expression of well-being and contentment on his face.

Sometimes,—though rarely,—the patient is cured on the spot; at other times, and this is more generally the case, he finds himself relieved, his pain or his depression has partially or totally disappeared, though only for a certain lapse of time.

In every case it is necessary to renew the suggestions more or less frequently according to your subject, being careful always to space them out at longer and longer intervals, according to the progress obtained until they are no longer necessary, that is to say when the cure is complete.

Before sending away your patient, you must tell him that he carries within him the instrument by which he can cure himself, and that you are, as it were, only a pro-

fessor teaching him to use this instrument, and that he must help you in your task. Thus, every morning before rising, and every night on getting into bed, he must shut his eyes and in thought transport himself into your presence, and then repeat twenty times consecutively in a monotonous voice, counting by means of a string with twenty knots in it, this little phrase:

"EVERY DAY. *IN EVERY RESPECT,* I AM GETTING BETTER AND BETTER." In his mind he should emphasize the words *"in every respect"* which applies to every need, mental or physical. This general suggestion is more efficacious than special ones.

Thus it is easy to realize the part played by the giver of the suggestions. He is not a master who gives orders, but a friend, a guide, who leads the patient step by step on the road to health. As all the suggestions are given in the interest of the patient, the unconscious of the latter asks nothing better than to assimilate them and transform them into autosuggestions. When this has been done, the cure is obtained more or less rapidly according to circumstances.

THE SUPERIORITY OF THIS METHOD

This method gives absolutely marvellous results, and it is easy to understand why. Indeed, by following out my advice, it is impossible to fail, except with the two classes of persons mentioned above, who fortunately represent barely 3 per cent of the whole. If, however you try to put your subjects to sleep right away, without the explanations and preliminary experiments necessary to bring them to accept the suggestions and to transform it into autosuggestion, you cannot and will not succeed except with peculiarly sensitive subjects, and these are rare. Everybody may become so by training, but very few are so sufficiently without the preliminary instruction that I recommend, which can be done in a few minutes.

Formerly, imagining that suggestions could only be given during sleep, I always tried to put my patient to sleep; but on discovering that it was not indispensable, I left off doing it in order to spare him the dread and uneasiness he almost always experiences when he is told that he is going to be sent to sleep, and which often makes him offer, in spite of himself, an involuntary resistance. If, on the contrary, you tell him that you are not going to put him to sleep as there is no need to do so, you gain his confidence, He listens to you without fear or any ulterior thought, and it often happens—if not the first time, anyhow very soon—that, soothed by the monotonous sound of your voice, he falls into a deep sleep from which he awakes astonished at having slept at all.

If there are sceptics among you—as I am quite sure there are—all I have to say to them is: "Come to my house and see what is being done, and you will be convinced by fact."

You must not however run away with the idea that autosuggestion can only be brought about in the way I have described. It is possible to make suggestions to people without their knowledge and without any preparation. For instance, if a doctor who by his title alone has a suggestive influence on his patient, tells him that he can do nothing for him, and that his illness is incurable, he provokes in the mind of the latter an autosuggestion which may have the most disastrous consequences; if however he tells him that his illness is a serious one, it is true, but that with care, time, and patience, he can be cured, he sometimes and even often obtains results which will surprise him.

Here is another example: if a doctor after examining his patient, writes a prescription and gives it to him without any comment, the remedies prescribed will not have much chance of succeeding; if, on the other hand, he explains to his patient that such and such medicines must be taken in such and such conditions and that they will pro-

duce certain results, those results are practically certain to be brought about.

If in this hall there are medical men or brother chemists, I hope they will not think me their enemy, I am on the contrary their best friend. On the one hand I should like to see the theoretical and practical study of suggestion on the syllabus of the medical schools for the great benefit of the sick and of the doctors themselves; and on the other hand, in my opinion, every time that a patient goes to see his doctor, the latter should order him one or even several medicines, even if they are not necessary. As a matter of fact, when a patient visits his doctor, it is in order to be told what medicine will cure him. He does not realize that it is the hygiene and regimen which do this, and he attaches little importance to them. It is a medicine that he wants.

In my opinion, if the doctor only prescribes a regimen without any medicine, his patient will be dissatisfied; he will say that he took the trouble to consult him for nothing, and often goes to another doctor. It seems to me then that the doctor should always prescribe medicines to his patient, and, as much as possible, medicines made up by himself rather than the standard remedies so much advertised and which owe their only value to the advertisement. The doctor's own prescriptions will inspire infinitely more confidence than So and So's pills which anyone can procure easily at the nearest drug store without any need of a prescription.

HOW SUGGESTION WORKS

In order to understand properly the part played by suggestion or rather by autosuggestion, it is enough to know that the *unconscious self is the grand director of all our functions.* Make this believed, as I said above, that a certain organ which does not function well must perform its function, and instantly the order is transmitted. The or-

gan obeys with docility, and either at once or little by little performs its functions in a normal manner. This explains simply and clearly how by means of suggestion one can stop hæmorrhages, cure constipation, cause fibrous tumours to disappear, cure paralysis, tubercular lesions, varicose, ulcers, etc.

Let us take for example, a case of dental hæmorrhage which I had the opportunity of observing in the consulting room of M. Gauthé, a dentist at Troyes. A young lady whom I had helped to cure herself of asthma from which she had suffered for eight years, told me one day that she wanted to have a tooth out. As I knew her to be very sensitive, I offered to make her feel nothing of the operation. She naturally accepted with pleasure and we made an appointment with the dentist. On the day we had arranged we presented ourselves at the dentist's and, standing opposite my patient, I looked fixedly at her, saying: "You feel nothing, you feel nothing, etc., etc." and then while still continuing the suggestion I made a sign to the dentist. In an instant the tooth was out without Mlle. D———— turning a hair. As fairly often happens, a hæmorrhage followed, but I told the dentist that I would try suggestion without his using a haemostatic, without knowing beforehand what would happen. I then asked Mlle. D. to look at me fixedly, and I suggested to her that in two minutes the hæmorrhage would cease of its own accord, and we waited. The patient spat blood again once or twice, and then ceased. I told her to open her mouth, and we both looked and found that a clot of blood had formed in the dental cavity.

How is this phenomena to be explained? In the simplest way. Under the influence of the idea: "The hæmorrhage is to stop", the unconscious had sent to the small arteries and veins the order to stop the flow of blood, and, obediently, they contracted *naturally,* as they would have done artificially at the contact of a hæmostatic like adrenalin, for example.

The same reasoning explains how a fibrous tumour can

be made to disappear. The *unconscious* having accepted the idea "It is to go" the brain orders the arteries which nourish it, to contract. They do so, refusing their services, and ceasing to nourish the tumour which, deprived of nourishment, dies, dries up, is reabsorbed and disappears.

THE USE OF SUGGESTION FOR THE CURE OF MORAL AILMENTS AND TAINTS EITHER CONGENITAL OR ACQUIRED

Neurasthenia, so common nowadays, generally yields to suggestion constantly practised in the way I have indicated. I have had the happiness of contributing to the cure of a large number of neurasthenics with whom every other treatment had failed. One of them had even spent a month in a special establishment at Luxemburg without obtaining any improvement. In six weeks he was completely cured, and he is now the happiest man one would wish to find, after having thought himself the most miserable. Neither is he ever likely to fall ill again in the same way, for I showed him how to make use of conscious autosuggestion and he does it marvellously well.

But if suggestion is useful in treating moral complaints and physical ailments, may it not render still greater services to society, in turning into honest folks the wretched children who people our reformatories and who only leave them to enter the army of crime. Let no one tell me it is impossible. The remedy exists and I can prove it.

I will quote the two following cases which are very characteristic, but here I must insert a few remarks in parenthesis. To make you understand the way in which suggestion acts in the treatment of moral taints I will use the following comparison. Suppose our brain is a plank in which are driven nails which represent the ideas, habits, and instincts, which determine our actions. If we find that there exists in a subject a bad idea, a bad habit, a bad instinct,—as it were, a bad nail, we take another which is

the good idea, habit, or instinct, place it on top of the bad one and give a tap with a hammer—in other words we make a suggestion. The new nail will be driven in perhaps a fraction of an inch, while the old one will come out to the same extent. At each fresh blow with the hammer, that is to say at each fresh suggestion, the one will be driven in a fraction further and the other will be driven out the same amount, until, after a certain number of blows, the old nail will come out completely and be replaced by the new one. When this substitution has been made, the individual obeys it.

Let us return to our examples. Little M————, a child of eleven living at Troyes, was subject night and day to certain accidents inherent to early infancy. He was also a kleptomaniac, and, of course, untruthful into the bargain. At his mother's request I treated him by suggestion. After the first visit the accidents ceased by day, but continued at night. Little by little they became less frequent, and finally, a few months afterwards, the child was completely cured. In the same period his thieving propensities lessened, and in six months they had entirely ceased.

This child's brother, aged eighteen, had conceived a violent hatred against another of his brothers. Every time that he had taken a little too much wine, he felt impelled to draw a knife and stab his brother. He felt that one day or other he would end by doing so, and he knew at the same time that having done so he would be inconsolable. I treated him also by suggestion, and the result was marvellous. After the first treatment he was cured. His hatred for his brother had disappeared, and they have since become good friends and got on capitally together. I followed up the case for a long time, and the cure was permanent.

Since such results are to be obtained by suggestion, would it not be beneficial—I might even say *indispensable* —to take up this method and introduce it into our reformatories? I am absolutely convinced that if suggestion were daily applied to vicious children, more than 50 per cent

could be reclaimed. Would it not be an immense service to render society, to bring back to it sane and well members of it who were formerly corroded by moral decay?

Perhaps I shall be told that suggestion is a dangerous thing, and that it can be used for evil purposes. This is no valid objection, first because the practice of suggestion would only be confided to reliable and honest people,—to the reformatory doctors, for instance,—and on the other hand, those who seek to use it for evil ask no one's permission.

But even admitting that it offers some danger (which is not so) I should like to ask whoever proffers the objection, to tell me what thing we use that is not dangerous? Is it steam? gunpowder? railways? ships? electricity? automobiles? aeroplanes? Are the poisons which we, doctors and chemists, use daily in minute doses, and which might easily destroy the patient if, in a moment's carelessness, we unfortunately made a mistake in weighing them out?

A FEW TYPICAL CURES

This little work would be incomplete if it did not include a few examples of the cures obtained. It would take too long, and would also perhaps be somewhat tiring if I were to relate all those in which I have taken part. I will therefore content myself by quoting a few of the most remarkable.

Mlle. M—— D——, of Troyes, had suffered for eight years from asthma which obliged her to sit up in bed nearly all night, fighting for breath. Preliminary experiments show that she is a very sensitive subject. She sleeps immediately, and the suggestion is given. From the first treatment there is an enormous improvement. The patient has a good night, only interrupted by one attack of asthma which only lasts a quarter of an hour. In a very short time the asthma disappears completely and there is no relapse later on.

M. M——, a working hosier living at Sainte-Savine near

Troyes, paralyzed for two years as the result of injuries at the junction of the spinal column and the pelvis. The paralysis is only in the lower limbs, in which the circulation of the blood has practically ceased, making them swollen, congested, and discolored. Several treatments, including the antisyphilitic, have been tried without success. Preliminary experiments successful; suggestion applied by me, and auto-suggestion by the patient for eight days. At the end of this time there is an almost imperceptible but still appreciable movement of the left leg. Renewed suggestion. In eight days the improvement is noticeable. Every week or fortnight there is an increased improvement with progressive lessening of the swelling, and so on. Eleven months afterwards, on the first of November, 1906, the patient goes downstairs alone and walks 800 yards, and in the month of July, 1907, goes back to the factory where he has continued to work since that time, with no trace of paralysis.

M. A—— G——, living at Troyes, has long suffered from enteritis, for which different treatments have been tried in vain. He is also in a very bad state mentally, being depressed, gloomy, unsociable, and obsessed by thoughts of suicide. Preliminary experiments easy, followed by suggestion which produces an appreciable result from the very day. For three months, daily suggestions to begin with, then at increasingly longer intervals. At the end of this time, the cure is complete, the enteritis has disappeared, and his *morals* have become excellent. As the cure dates back twelve years without the shadow of a relapse, it may be considered as permanent. M. G——, is a striking example of the effects that can be produced by suggestion, or rather by auto-suggestion. At the same time as I made suggestions to him from the physical point of view, I also did so from the mental, and he accepted both suggestions equally well. Every day his confidence in himself increased, and as he was an excellent workman, in order to earn more, he looked out for a machine which would enable him to work at home for his employer. A

little later a factory owner having seen with his own eyes what a good workman he was, entrusted him with the very machine he desired. Thanks to his skill he was able to turn out much more than an ordinary workman, and his employer, delighted with the result, gave him another and yet another machine, until M. G——, who, but for suggestion, would have remained an ordinary workman, is now in charge of six machines which bring him a very handsome profit.

Mme. D——, at Troyes, about 30 years of age. She is in the last stages of consumption, and grows thinner daily in spite of special nourishment. She suffers from coughing and spitting, and has difficulty in breathing; in fact, from all appearances she has only a few months to live. Preliminary experiments show great sensitiveness, and suggestion is followed by immediate improvement. From the next day the morbid symptoms begin to lessen. Every day the improvement becomes more marked, the patient rapidly puts on flesh, although she no longer takes special nourishment. In a few months the cure is apparently complete. This person wrote to me on the 1st of January, 1911, that is to say eight months after I had left Troyes, to thank me and to tell me that, although pregnant, she was perfectly well.

I have purposely chosen these cases dating some time back, in order to show that the cures are permanent, but I should like to add a few more recent ones.

M. X——, Post Office clerk at Lunéville. Having lost one of his children in January, 1910, the trouble produces in him a cerebral disturbance which manifests itself by uncontrollable nervous trembling. His uncle brings him to me in the month of June. Preliminary experiments followed by suggestion. Four days afterwards the patient returns to tell me that the trembling has disappeared. I renew the suggestion and tell him to return in eight days. A week, then a fortnight, then three weeks, then a month, pass by without my hearing any more of him. Shortly afterwards his uncle comes and tells me that he has just

had a letter from his nephew, who is perfectly well. He has taken on against his work as telegraphist which he had been obliged to give up, and the day before, he had sent off a telegram of 170 words without the least difficulty. He could easily, he added in his letter, have sent off an even longer one. Since then he has had no relapse.

M. Y——, of Nancy, has suffered from neurasthenia for several years. He has aversions, nervous fears, and disorders of the stomach and intestines, he sleeps badly, is gloomy and is haunted by ideas of suicide; he staggers when he walks like a drunken man, and can think of nothing but his trouble. All treatments have failed and he gets worse and worse; a stay in a special nursing home for such cases has no effect whatever. M. Y—— comes to see me at the beginning of October, 1910. Preliminary experiments comparatively easy. I explain to the patient the principles of autosuggestion, and the existence within us of the conscious and the unconscious self, and then make the required suggestion. For two or three days M. Y—— has a little difficulty with the explanations I have given him. In a short time light breaks in upon his mind, and he grasps the whole thing. I renew the suggestion, and he makes it himself too every day. The improvement, which is at first slow, becomes more and more rapid, and in a month and a half the cure is complete. The ex-invalid who had lately considered himself the most wretched of of men, now thinks himself the happiest.

M. E——, of Troyes. An attack of gout; the right ankle is inflamed and painful, and he is unable to walk. The preliminary experiments show him to be a very sensitive subject. After the first treatment he is able to regain, without the help of his stick, the carriage which brought him, and the pain has ceased. The next day he does not return as I had told him to do. Afterwards his wife comes alone and tells me that that morning her husband had got up, put on his shoes, and gone off on his bicycle to visit his yards (he is a painter). It is needless to tell you my utter astonishment. I was not able to follow

up this case, as the patient never deigned to come and see me again, but some time afterward I heard that he had had no relapse.

Mme. T——, of Nancy. Neurasthenia, dyspepsia, gastralgia, enteritis, and pains in different parts of the body. She has treated herself for several years with a negative result. I treat her by suggestion, and she makes autosuggestions for herself every day. From the first day there is a noticeable improvement which continues without interruption. At the present moment this person has long been cured mentally and physically, and follows no regimen. She thinks that she still has perhaps a slight touch of enteritis, but she is not sure.

Mme. X——, a sister of Mme. T——. Acute neurasthenia; she stays in bed a fortnight every month, as it is totally impossible for her to move or work; she suffers from lack of appetite, depression, and digestive disorders. She is cured by one visit, and the cure seems to be permanent as she has had no relapse.

Mme. H——, at Maxéville. General eczema, which is particularly severe on the left leg. Both legs are inflamed, above all at the ankles, walking is difficult and painful. I treat her by suggestion. That same evening Mme. H—— is able to walk several hundred yards without fatigue. The day after the feet and ankles are no longer swollen and have not been swollen again since. The eczema disappears rapidly.

Mme. P——, at Laneuveville. Pains in the kidneys and the knees. The illness dates from ten years back and is becoming worse every day. Suggestion from me, and autosuggestion from herself. The improvement is immediate and increases progressively. The cure is obtained rapidly, and is a permanent one.

Mme. Z——, of Nancy, felt ill in January, 1910, with congestion of the lungs, from which she had not recovered two months later. She suffers from general weakness, loss of appetite, bad digestive trouble, rare and difficult bowel action, insomnia, copious night-sweats. After the first sug-

gestion, the patient feels much better, and two days later she returns and tells me that she feels quite well. Every trace of illness has disappeared, and all the organs are functioning normally. Three or four times she had been on the point of sweating, but each time prevented it by the use of conscious auto-suggestion. From this time Mme. Z—— has enjoyed perfectly good health.

M. X——, at Belfort, cannot talk for more than ten minutes or a quarter of an hour without becoming completely aphonous. Different doctors consulted find no lesion in the vocal organs, but one of them says that M. X—— suffers from senility of the larynx, and this conclusion confirms him in the belief that he is incurable. He comes to spend his holidays at Nancy, and a lady of my acquaintance advises him to come and see me. He refuses at first, but eventually consents in spite of his absolute disbelief in the effects of suggestion. I treat him in this way nevertheless, and ask him to return two days afterwards. He comes back on the appointed day, and tells me that the day before he was able to converse the whole afternoon without becoming aphonous. Two days later he returns again to say that his trouble had not reappeared, although he had not only conversed a great deal but even sung the day before. The cure still holds good and I am convinced that it will always do so.

Before closing, I should like to say a few words on the application of my method to the training and correction of children by their parents.

The latter should wait until the child is asleep, and then one of them should enter his room with precaution, stop a yard from his bed, and repeat 15 or 20 times in a murmur all the things they wish to obtain from the child, from the point of view of health, work, sleep, application, conduct, etc. He should then retire as he came, taking great care not to awake the child. This extremely simple process gives the best possible results, and it is easy to understand why. When the child is asleep his body and his conscious are at rest and, as it were, annihilated; his uncon-

scious self however is awake; it is then to the latter alone that one speaks, and as it is very credulous it accepts what one says to it without dispute, so that, little by little, the child arrives at making of himself what his parents desire him to be.

CONCLUSION

What conclusion is to be drawn from all this?

The conclusion is very simple and can be expressed in a few words: We possess within us a force of incalculable power, which, when we handle it unconsciously is often prejudicial to us. If on the contrary we direct it in a conscious and wise manner, it gives us the mastery of ourselves and allows us not only to escape and to aid others to escape, from physical and mental ills, but also to live in relative happiness, whatever the conditions in which we may find ourselves.

Lastly, and above all, it should be applied to the moral regeneration of those who have wandered from the right path.

EMILE COUÉ.

THE MIRACLE WITHIN

(Reprinted from the "Renaissance politique, littéraire et artistique" of the 18th of December, 1920)

HOMAGE TO EMILE COUÉ

In the course of the month of September, 1920, I opened for the first time the book of Charles Baudouin, of Geneva, professor at the Institute J.J. Rousseau in that town.

This work, published by the firm of Delachaux and Niestlé, 26, rue Saint-Dominique, Paris, is called: "Suggestion et Autosuggestion". The author has dedicated it: *"To Emile Coué, the initiator and benefactor, with deep gratitude".*

I read it and did not put down the book until I had reached the end.

The fact is that it contains the very simple exposition of a magnificently humanitarian work, founded on a theory which may appear childish just because it is within the scope of everyone. And if everyone puts it into practice, the greatest good will proceed from it.

After more than twenty years of indefatigable work, Emile Coué who at the present time lives at Nancy, where he lately followed the work and experiments of Liébault, the father of the doctrine of suggestions, for more than twenty years, I say, Coué has been occupied exclusively with this question, but particularly in order to bring his fellow creatures to cultivate *auto-suggestion.*

At the beginning of the century Coué had attained the object of his researches, and had disengaged the general and immense force of autosuggestion. After innumerable experiments on thousands of subjects, *he showed the action of the unconscious in organic cases.* This is new, and the great merit of this profoundly, modest learned man, is to have found a remedy for terrible ills, reputed incurable or terribly painful, without any hope of relief.

As I cannot enter here into long scientific details I will content myself by saying how the learned man of Nancy practises his method.

The chiselled epitome of a whole life of patient researches and of ceaseless observations, is a brief formula which is to be repeated morning and evening.

It must be said in a low voice, with the eyes closed, in a position favourable to the relaxing of the muscular system, it may be in bed, or it may be in an easy chair, and in a tone of voice as if one were reciting a litany.

Here are the magic words: *"Every day, in every respect, I am getting better and better".*

They must be said twenty times following, with the help of a string with twenty knots in it, which serves as a rosary. This material detail has its importance: it ensures mechanical recitation, which is essential.

While articulating these words, *which are registered by the unconscious,* one must not think of anything particular, neither of one's illness nor of one's troubles, one must be passive, just with the desire that all may be for the best. The formula *"in every respect"* has a general effect.

This desire must be expressed without passion, without will, with gentleness, *but with absolute confidence.*

For Emile Coué at the moment of autosuggestion, *does not call in the will in any way, on the contrary;* there must be no question of the will at that moment, but the *imagination,* the great motive force infinitely more active than that which is usually invoked, the imagination alone must be brought into play.

"Have confidence in yourself" says this good cousellor, "believe firmly that all will be well". And indeed all is well for those who have faith, fotified by perseverance.

As deeds talk louder than words, I will tell you what happened to myself before I had ever seen M. Coué.

I must go back then to the month of September when I opened M. Charles Baudouin's volume. At the end of a substantial exposition, the author enumerates the cure of

illnesses such as enteritis, eczema, stammering, dumbness, a sinus dating from twenty years back which had necessitated eleven operations, metritis, salpingitis, fibrous tumours, varicose, veins, etc., lastly and above all, deep tubercular sores, and the last stages of phthisis (case of Mme. D——, of Troyes, aged 30 years, who has become a mother since her cure; case was followed up, but there was no relapse). All this is often testified to by doctors in attendance on the patients.

These examples impressed me profoundly; *there* was the miracle. It was not a question of nerves, but of ills which medicine attacks without success. This cure of tuberculosis was a revelation to me.

Having suffered for two years from acute neuritis in the face, I was in horrible pain. Four doctors, two of them specialists, had pronounced the sentence which would be enough, of itself alone, to increase the trouble by its fatal influence on the mind: "Nothing to be done!" This "nothing to be done" had been for me the worst of auto-suggestions.

In possession of the formula: "Every day, in every respect...", etc., I recited it with a faith which, although it had come suddenly, was none the less capable of removing mountains, and throwing down shawls and scarves, bareheaded, I went into the garden in the rain and wind repeating gently: *"I am going to be cured,* I shall have no more neuritis, it is going away, it will not come back, etc. . .". The next day I was cured and never any more since have I suffered from this abominable complaint, which did not allow me to take a step out of doors and made life unbearable. It was an immense joy. The incredulous will say: "It was all nervous." Obviously, and I give them this first point. But, delighted with the result, I tried the Coué Method for an oedema of the left ankle, resulting from an affection of the kidneys reputed incurable. In two days the oedema had disappeared. I then treated fatigue and mental depression, etc., and extraordinary improvement was produced, and I had but one idea: to go to Nancy to thank my benefactor.

I went there and found the excellent man, attractive by his goodness and simplicity, who has become my friend.

It was indispensable to see him in his field of action. He invited me to a popular "séance." I heard a concert of gratitude. Lesions in the lungs, displaced organs, asthma, Pott's disease (!), paralysis, the whole deadly horde of diseases were being put to flight. I saw a paralytic, who sat contorted and twisted in his chair, get up and walk. M. Coué had spoken, he demanded confidence, great, immense confidence in oneself. He said: "Learn to cure yourselves, you can do so; I have never cured anyone. The power is within you yourselves, call upon your spirit, make it act for your physical and mental good, and it will come, it will cure you, you will be strong and happy". Having spoken, Coué approached the paralytic: "You heard what I said, do you believe that you will walk?" "Yes."—"Very well then, get up!" The woman got up, she walked, and went round the garden. The miracle was accomplished.

A young girl with Pott's disease, whose vertebral column became straight again after three visits, told me what an intense happiness it was to feel herself coming back to life after having thought herself a hopeless case.

Three women, cured of lesions in the lungs, expressed their delight at going back to work and to a normal life. Coué in the midst of those people whom he loves, seemed to me a being apart, for this man ignores money, all his work is gratuitous, and his extraordinary disinterestedness forbids his taking a farthing for it. "I owe you something", I said to him ,"I simply owe you everything..." "No, only the pleasure I shall have from your continuing to keep well..."

An irresistible sympathy attracts one to this simple-minded philanthropist; arm in arm we walked round the kitchen garden which he cultivates himself, getting up early to do so. Practically a vegetarian, he considers with satisfaction the results of his work. And then the serious conversation goes on: "In your *mind* you possess an *un-*

limited power. It acts on matter if we know how to domesticate it. The imagination is like a horse without a bridle; if such a horse is pulling the carriage in which you are, he may do all sorts of foolish things and take you to your death. But harness him properly, drive him with a sure hand, and he will go wherever you like. Thus it is with the mind, the imagination. They must be directed for our own good. Autosuggestion, formulated with the lips, is an order which the unconscious receives, it carries it out unknown to ourselves and above all at night, so that the evening auto-suggestion is the most important. It gives marvellous results.

When you feel a physical pain, add the formula *"It is going away..."*, very quickly repeated, in a kind of droning voice, placing your hand on the part where you feel the pain, or on the forehead, if it is a mental distress.

For the method acts very efficaciously on the mind. After having called in the help of the soul for the body, one can ask it again for all the circumstances and difficulties of life.

There also I know from experience that events can be singularly modified by this process.

You know it to-day, and you will know it better still by reading M. Baudouin's book, and then his pamphet: *"Culture de la force morale"*, and then, lastly, the little succinct treatise written by M. Coué himself: *"Self Mastery."* All these works may be found at M. Coué's.

If however I have been able to inspire in you the desire of making this excellent pilgrimage yourself, you will go to Nancy to fetch the booklet. Like myself you will love this unique man, unique by reason of his noble charity and of his love for his fellows, as Christ taught it.

Like myself also, you will be cured physically and mentally. Life will seem to you better and more beautiful. That surely is worth the trouble of trying for.

M. Burnat-Provins.

THOUGHTS AND PRECEPTS OF M. EMILE COUÉ

taken down literally by Mme. Emile LEON, his disciple.

Do not spend your time in thinking of illnesses you might have, for if you have no real ones you will create artificial ones.

*
* *

When you make conscious autosuggestions, do it naturally, simply, with conviction, and above all *without any effort.* If unconscious and bad autosuggestions are so often realized, it is because they are made without effort.

*
* *

Be sure that you will obtain what you want, and you will obtain it, so long as it is within reason.

*
* *

To become master of oneself it is enough to think that one is becoming so... Your hands tremble, your steps falter, tell yourself that all that is going to cease, and little by little it will disappear. It is not in me but in yourself that you must have confidence, for it is in yourself alone that dwells the force which can cure you. My part simply consists in teaching you to make use of that force.

*
* *

Never discuss things you know nothing about, or you will only make yourself ridiculous.

Things which seem miraculous to you have a perfectly natural cause; if they seem extraordinary, it is only be-

cause the cause escapes you. When you know that, you realize that nothing could be more natural.

*
* *

When the will and the imagination are in conflict, it is always the imagination which wins. Such a case is only too frequent, and then not only do we not do what we want, but just the contrary of what we want. For example: the more we try to go to sleep, the more we try to remember the name of some one, the more we try to stop laughing, the more we try to avoid an obstacle, while *thinking that we cannot do so*, the more excited we become, the less we can remember the name, the more uncontrollable our laughter becomes, and the more surely we rush upon the obstacle.

It is then the imagination and not the will which is the most important faculty of man; and thus it is a serious mistake to advise people to train their wills, it is the training of their imaginations which they ought to set about.

*
* *

Things are not for us what they are, but what they seem; this explains the contradictory evidence of persons speaking in all good faith.

*
* *

By believing oneself to be the master of one's thoughts one becomes so.

*
* *

Everyone of our thoughts, good or bad, becomes concrete, materializes, and becomes in short a reality.

We are what we make ourselves and not what circumstances make us.

*
* *

Whoever starts off in life with the idea: "I shall succeed", always does succeed because he does what is necessary to bring about this result. If only one opportunity presents itself to him, and if this opportunity has, as it were, only one hair on its head, he seizes it by that one hair. Further, he often brings about unconsciously or not, propitious circumstances.

He who on the contrary always doubts himself, never succeeds in doing anything. He might find himself in the midst of an army of opportunities with heads of hair like Absalom, and yet he would not see them and could not seize a single one, even if he had only to stretch out his hand in order to do so. And if he brings about circumstances, they are generally unfavorable ones. Do not then blame fate, you have only yourself to blame.

*
* *

People are always preaching the doctrine of effort, but this idea must be repudiated. Effort means will, and will means the possible entrance of the imagination in opposition, and the bringing about of the exactly contrary result to the desired one.

*
* *

Always think that what you have to do is easy, if possible. In this state of mind you will not spend more of your strength than just what is necessary; if you consider it difficult, you will spend ten, twenty times more strength than you need; in other words you will waste it.

*
* *

Auto-suggestion is an instrument which you have to

learn how to use just as you would for any other instrument. An excellent gun in inexperienced hands only gives wretched results, but the more skilled the same hands become, the more easily they place the bullets in the target.

*
* *

Conscious auto-suggestion, made with confidence, with faith, with perseverance, realizes itself mathematically, within reason.

*
* *

When certain people do not obtain satisfactory results with autosuggestion, it is either because they lack confidence, or because they make efforts, which is the more frequent case. To make good suggestions it is absolutely necessary to do it *without effort.* The latter implies the use of the *will,* which must be entirely put aside. One must have recourse *exclusively* to the imagination.

*
* *

Many people who have taken care of their health all their life in vain, imagine that they can be immediately cured by autosuggestion. It is a mistake, for it is not reasonable to think so. It is no use expecting from suggestion more than it can normally produce, that is to say, a progressive improvement which little by little transforms itself into a complete cure, when that is possible.

*
* *

The means employed by the healers all go back to autosuggestion, that is to say that these methods, whatever they are: words, incantations, gestures, staging, all produce in the patient the autosuggestion of recovery.

Every illness has two aspects (unless it is exclusively a mental one. Indeed, on every physical illness a mental one comes and attaches itself. If we give to the physical illness the coefficient 1, the mental illness may have the coefficient 1, 2, 10, 20, 50, 100, and more. In many cases this can disappear instantaneously, and if its coefficient is a very high one, 100 for instance, while that of the physical ailment is 1, only this latter is left, a 101st of the total illness; such a thing is called a miracle, and yet there is nothing miraculous about it.

*
* *

Contrary to common opinion, physical diseases are generally far more easily cured than mental ones.

Buffon used to say: "Style is the man." We would put in that: "Man is what he thinks". The fear of failure is almost certain to cause failure, in the same way as the idea of success brings success, and enables one always to surmount the obstacles that may be met with.

*
* *

Conviction is as necessary to the suggester as to his subject. It is this conviction, this faith, which enables him to obtain results where all other means have failed.

*
* *

It is not the person who acts, it is the method.

*
* *

... Contrary to general opinion, suggestion, or auto-suggestion can bring about the cure of organic lesions.

Formerly it was believed that hypnotism could only be applied to the treatment of nervous illnesses; its domain

is far greater than that. It is true that hypnotism acts through the intermediary of the nervous system; but the nervous system dominates the whole organism. The muscles are set in movement by the nerves; the nerves regulate the circulation by their direct action on the heart, and by their action on the blood vessels which they dilate or contract. The nerves act then on all the organs, and by their intermediation all the unhealthy organs may be affected.

Docteur Paul Joire,
Président of the Société universelle d'Etudes psychiques
(Bull. No. 4 of the S. L. P.)

*
* *

... Moral influence has a considerable value as a help in healing. It is a factor of the first order which it would be very wrong to neglect, since in medicine as in every branch of human activity it is the *spiritual forces* which lead the world.

Docteur Louis Renon,
Lecturing professor at the Faculty of Medicine of Paris, and doctor at the Necker Hospital.

*
* *

... Never lose sight of the great principle of autosuggestion: *Optimism always and in spite of everything, even when events do not seem to justify it.*

René de Drabois,
(Bull. 11, of the S. L. P. A.)

*
* *

Suggestion sustained by faith is a formidable force.
Docteur A. L., Paris. (July, 1920.)

To have and to inspire unalterable confidence, one must walk with the assurance of perfect sincerity, and in order to possess this assurance and sincerity, one must wish for *the good of others* more than one's own.

"Culture de la Force Morale", by C. BAUDOUIN

OBSERVATIONS

Young B——, 13 years old, enters the hospital in January 1912. He has a very serious heart complaint characterized by a peculiarity in the respiration; he has such difficulty in breathing that he can only take very slow and short steps. The doctor who attends him, one of our best practitioners, predicts a rapid and fatal issue. The invalid leaves the hospital in February, *no better.* A friend of his family brings him to me and when I see him I regard him as a hopeless case, but nevertheless I make him pass through the preliminary experiments which are marvellously successful. After having made him a suggestion and advised him to do the same thing for himself, I tell him to come back in two days. When he does so I notice to my astonishment a *remarkable* improvement in his respiration and his walking. I renew the suggestion and two days afterwards, when he returns the improvement has continued, and so it is at every visit. So rapid is the progress that he makes that, three weeks after the first visit, my little patient is able to go *on foot* with his mother to the plateau of Villers. He can breathe with ease and almost normally, he can walk without getting out of breath, and can mount the stairs, which was impossible for him before. As the improvement is steadily maintained, little B... asks me if he can go and stay with his grandmother at Carignan. As he seems well I advise him to do so, and he goes off, but sends me news of himself from time to time. His health is becoming better and better, he has a good appetite, digests and assimilates his food well, and the feeling of oppression has entirely disappeared. Not only can he walk like everybody else, but he even runs and chases butterflies.

He returns in October, and I can hardly recognize him, for the bent and puny little fellow who had left me in May

has become a tall upright boy, whose face beams with health. He has grown 12 centimetres and gained 19 lbs. in weight. Since then he has lived a perfectly normal life; he runs up and down stairs, rides a bicycle, and plays football with his comrades.

Mlle. X——, of Geneva, aged 13. Sore on the temple considered by several doctors as being of tubercular origin; for a year and a half it has refused to yield to the different treatments ordered. She is taken to M. Baudouin, a follower of M. Couè at Geneva, who treats her by suggestion and tells her to return in a week. When she comes back the sore has healed.

Mlle. Z——, also of Geneva. Has had the right leg drawn up for 17 years, owing to an abscess above the knee which had had to be operated upon. She asks M. Baudouin to treat her by suggestion, and hardly has he begun when the leg can be bent and unbent in a normal manner. (There was of course a psychological cause in this case.)

Mme. Urbain Marie, aged 55, at Maxéville. Varicose ulcer, dating from more than a year and a half. First visit in September 1915, and a second one a week later. In a fortnight the cure is complete.

Emile Chenu, 10 years old, Grande-Rue, 19 (a refugee from Metz). Some unknown heart complaint with vegetations. Every night loses blood by the mouth. Comes first in July 1915, and after a few visits the loss of blood diminishes, and continues to do so until by the end of November it has ceased completely. The vegetations also seem to be no longer there, and by August 1916 there had been no relapse.

M. Hazot, aged 48, living at Brin. Invalided the 15th of January 1915 with *specific* chronic bronchitis, which is getting worse every day. He comes in to me in October, 1915. The improvement is immediate, and has been maintained since. At the present moment, although he is not completely cured, he is very much better.

M. B.——, Has suffered for 24 years from a frontal

sinus, which had necessitated eleven operations!! In spite of all that had been done the sinus persisted, accompanied by intolerable pains. The physical state of the patient was pitiable in the extreme; he had violent and almost continuous pain, extreme weakness; lack of appetite, could neither walk, read nor sleep, etc. His nerves were in nearly as bad a state as his body, and in spite of the treatment of such men as Bernheim of Nancy, Dèjerine of Paris, Dubois of Bern, X... of Strasburg, his ill health not only continued but even grew worse every day. The patient comes to me in September, 1915, on the advice of one of my other patients. From that moment he made rapid progress and at the present time (1921) he is perfectly well. It is a real resurrection.

M. Nagengast, aged 18, rue Sellier, 39. Suffering from Pott's disease. Comes to me in the beginning of 1914, having been encased for six months in a plaster corset. Comes regularly twice a week to the "seances", and makes for himself the usual suggestion morning and evening. Improvement soon shows itself, and in a short time the patient is able to do without his plaster casing. I saw him again in April 1916. He was completely cured, and was carrying on his duties as postman, after having been assistant to an ambulance at Nancy, where he had stayed until it was done away with.

M. D.——, at Jarville. Paralysis of the left upper eyelid. Goes to the hospital where he receives injections, as a result of which the eyelid is raised. The left eye was however deflected outwards for more than 45 degrees, and an operation seemed to be necessary. It was at this moment that he came to me, and thanks to autosuggestion the eye went back little by little to its normal position.

Mme. L——, of Nancy. Continuous pain in the right side of the face, which had gone on for 10 years. She has consulted many doctors whose prescriptions seem of no use, and an operation is judged to be necessary. The patient comes to me on the 25th of July 1916, and there is an immediate improvement. In about ten days' time the

pain has entirely vanished, and up to the 20th of December there had been no recurrence.

T—— Maurice, aged 8 and a half, at Nancy: club feet. A first operation cures, or nearly so, the left foot, while the right one still remains crippled. Two subsequent operations do no good. The child is brought to me for the first time in February 1915; he walks pretty well, thanks to two contrivances which hold his feet straight. The first visit is followed by an immediate improvement, and after the second, the child is able to walk in ordinary boots. The improvement becomes more and more marked, and by the 17th of April the child is quite well. The right foot however is not now quite so strong as it was, owing to a sprain which he gave it in February 1916.

Mlle X——, at Blainville. A sore on the left foot, probably of specific origin. A slight sprain has brought about a swelling of the foot accompanied by acute pains. Different treatments have only had a negative effect, and in a little while a suppurating sore appears which seems to indicate caries of the bone. Walking becomes more and more painful and difficult in spite of the treatment. On the advice of a former patient who had been cured, she comes to me, and there is noticeable relief after the first visits. Little by little the swelling goes down, the pain becomes less intense, the suppuration lessens, and finally the sore heals over. The process has taken a few months. At present the foot is practically normal, but although the pain and swelling have entirely disappeared, the back flexion of the foot is not yet perfect, which makes the patient limp slightly.

Mme. R——, of Chavigny. Metritis dating from 10 years back. Comes at the end of July 1916. Improvement is immediate, the pain and loss of blood diminish rapidly, and by the following 29th of September both have disappeared. The monthly period, which lasted from eight to ten days, is now over in four.

Mme. H——, rue Guilbert-de-Pivérécourt, at Nancy, aged 49. Suffers from a varicose ulcer dating from September

1914, which has treated according to her doctor's advice, but without success. The lower part of the leg is enormous (the ulcer, which is as large as a two franc piece and goes right down to the bone, is situated above the ankle). The inflammation is very intense, the suppuration copious, and the pains extremely violent. The patient comes for the first time in April 1916, and the improvement which is visible after the first treatment, continues without interruption. By the 18th of February, 1917, the swelling has *entirely subsided*, and the pain and irritation have disappeared. The sore is still there, but it is no larger than a pea and it is only a few millimetres in depth; it still discharges very slightly. By 1920 the cure has long been complete.

Mlle. D——, at Mirecourt, 16 years of age. Has suffered from attacks of nerves for three years. The attacks, at first infrequent, have gradually come at closer intervals. When she comes to see me on the 1st of April 1917, she has had three attacks in the preceding fortnight. Up to the 18th of April she did not have any at all. I may add that this young lady, from the time she began the treatment, was no longer troubled by the bad headaches from which she had suffered almost constantly.

Mme. M——, aged 43, rue d'Amance, 2, Malzéville, Comes at the end of 1916 for violent pains in the head from which she has suffered all her life. After a few visits they vanish completely. Two months afterwards she realized that she was also cured of a prolapse of the uterus which she had not mentioned to me, and of which she was not thinking when she made her autosuggestion. (This result is due to the words: *"in every respect"* contained in the formula used morning and evening.)

Mme. D——, Choisy-le-Roi. Only one general suggestion from me in July 1916, and autosuggestion on her part morning and evening. In October of the same year this lady tells me that she is cured of a prolapse of the uterus from which she had suffered for more than twenty years.

LEGISLATIVE LIBRARY ONTARIO

Up to April 1920 the cure is still holding good. (Same remark as in the preceding case.)

Mme. Jousselin, aged 60, rue des Dominicains, 6, Comes on the 20th of July 1917, for a violent pain in the right leg, accompanied by considerable swelling of the whole limb. She can only drag herself along with groans, but after the "séance", to her great astonishment, she can walk *normally* without feeling the least pain. When she comes back four days afterwards, she has had no return of the pain and the swelling has subsided. This patient tells me that since she has attended the "séances" she has also been cured of white discharges, and of enteritis from which she had long suffered. (Same remark as above.) In November the cure is still holding good.

Mlle. G. L.——, aged 15, rue du Montet, 88. Has stammered from infancy. Comes on the 20th of July 1917, and the stammering ceases instantly. A month later I saw her again and she had had no recurrence.

M. Ferry (Eugène), aged 60, rue de la Côte, 56. For five years has suffered from rheumatic pains in the shoulders and in the left leg. Walks with difficulty leaning on a stick, and cannot lift the arms higher than the shoulders. Comes on the 17th of September 1917. After the first "séance", the pains vanish completely and the patient can not only take long strides but even *run*. Still more, he can whirl both arms like a windmill. In November the cure is still holding good.

Mme. Lacour, aged 63, chemin des Sables. Pains in the face dating from more than twenty years back. All treatments have failed. An operation is advised, but the patient refuses to undergo it. She comes for the first time on July 25th 1916, and four days later the pain ceases. The cure has held good to this day.

Mme. Martin, Grande-Rue (Ville-Vieille), 105. Inflammation of the uterus of 13 years standing, accompanied by pains and white and red discharges. The period, which is very painful, recurs every 22 or 23 days and lasts 10-12 days. Comes for the first time on the 15th of November

1917 and returns regularly every week. There is visible improvement after the first visit, which continues rapidly until at the beginning of January 1918 the inflammation has entirely disappeared; the period comes at more regular intervals and without the slightest pain. A pain in the knee which the patient had had for 13 years was also cured.

Mme. Castelli, aged 41, living at Einville (M.-et M.). Has suffered from intermittent rheumatic pains in the right knee for 13 years. Five years ago she had a more violent attack than usual, the leg swells as well as the knee, then the lower part of the limb atrophies, and the patient is reduced to walking very painfully with the aid of a stick or crutch. She comes for the first time on the 5th of November 1917. She goes away *without the help of either crutch or stick.* Since then she no longer uses her crutch at all, but occasionally makes use of her stick. The pain in the knee comes back from time to time, but only very slightly.

Mme. Meder, aged 52, at Einville. For six months has suffered from pain in the right knee accompanied by swelling, which makes it impossible to bend the leg. Comes for the first time on Dec. 7th 1917. Returns on Jan. 4th 1918, saying that she has almost ceased to suffer and that she can walk normally. After that visit of the 4th, the pain ceases entirely, and the patient walks like other people.

EMILE COUÉ

A SURVEY OF THE "SÉANCES" AT M. COUÉ'S

The town thrills at this name, for from every rank of society people come to him and everyone is welcomed with the same benevolence, which already goes for a good deal. But what is extremely poignant is at the end of the séance to see the people who came in gloomy, bent, almost hostile (they were in pain), go away like everybody else; unconstrained, cheerful, sometimes radiant (they are no longer in pain!!). With a strong and smiling goodness of which he has the secret, M. Couè, as it were, holds the hearts of those who consult him in his hand; he addresses himself in turn to the numerous persons who come to consult him, and speaks to them in these terms:

"Well, Madame, and what is your trouble?..."

Oh, you are looking for too many whys and wherefores; what does the cause of your pain matter to you? You are in pain, that is enough... I will teach you to get rid of that...

And you, Monsieur, your varicose ulcer is already better. That is good, very good indeed, do you know, considering you have only been here twice; I congratulate you on the result you have obtained. If you go on doing your auto-suggestions properly, you will very soon be cured... You have had this ulcer for ten years, you say? What does that matter? You might have had it twenty and more, and it could be cured just the same.

And you say that you have not obtained any improvement?... Do you know why?... Simply because you lack confidence in yourself. When I tell you that you are better, you feel better at once, don't you? Why? Be-

cause you have faith in me. Just believe in yourself and you will obtain the same result.

Oh, Madame not so many details, I beg you! By looking out for the details you create them, and you would want a list a yard long to contain all your maladies. As a matter of fact, with you it is the mental outlook which is wrong. Well, make up your mind that it is going to get better and it will be so. It's as simple as the Gospel...

You tell me you have attacks of nerves every week... Well, from to-day you are going to do what I tell you and you will cease to have them...

You have suffered from constipation for a long time?... What does it matter how long it is?... You say it is forty years? Yes, I heard what you said, but it is none the less true that you can be cured to-morrow; you hear, to-morrow, on condition, naturally, of your doing exactly what I tell you to do, in the way I tell you to do it...

Ah! you have glaucoma, Madame. I cannot absolutely promise to cure you of that, for I am not sure that I can. That does not mean that you cannot be cured, for I have known it to happen in the case of a lady of Chalon-sur-Saône and another of Lorraine.

Well, Mademoiselle, as you have not had your nervous attacks since you came here, whereas you used to have them every day, you are cured. Come back sometimes all the same, so that I may keep you going along the right lines.

The feeling of oppression will disappear with the lesions which will disappear when you assimilate properly; that will come all in good time, but you mustn't put the cart before the horse... it is the same with oppression as with heart trouble, it generally diminishes very quickly...

Suggestion does not prevent you from going on with your usual treatment... As for the blemish you have on your eye, and which is lessening almost daily, the opacity and the size are both growing less every day.

To a child (in a clear and commanding voice): "Shut your eyes, I am not going to talk to you about lesions or anything else, you would not understand; the pain in your chest is going away, and you won't want to cough any more.

Observation.—It is curious to notice that all those suffering from chronic bronchitis are immediately relieved and their morbid symptoms rapidly disappear... Children are very easy and very obedient subjects; their organism almost always obeys immediately to suggestion.

To a person who complains of fatigue: "Well, so do I. There are also days when it tires me to receive people, but I receive them all the same and all day long. Do not say: *"I cannot help it". "One can always overcome oneself."*

Observation.—The idea of fatigue necessarily brings fatigue, and the idea that we have a duty to accomplish always gives us the *necessary* strength to fulfill it the mind can and must remain master of the animal side of our nature.

The cause which prevents you from walking, whatever it is, is going to disappear little by little every day: you know the proverb: *Heaven helps those who help themselves.* Stand up two or three times a day supporting yourself on two persons, and say to yourself firmly: *My kidneys are not so weak that I cannot do it, on the contrary I can...*

After having said: "Every day, in every respect, I am getting better and better", add: "The people who are pursuing me *cannot* pursue me any more, they are not pursuing me...

What I told you is quite true; it was enough to think that you had no more pain for the pain to disappear; *do not think then that it may come back or it will come back...*

(A woman, sotto voice, "What patience he has! What a wonderfully painstaking man!")

ALL THAT WE THINK BECOMES TRUE FOR US. WE MUST NOT THEN ALLOW OURSELVES TO THINK WRONGLY.

THINK "MY TROUBLE IS GOING AWAY", JUST AS YOU THINK YOU CANNOT OPEN YOUR HANDS.

The more you say: *"I will not"*, the more surely the contrary comes about. You must say: *"It is going away"*, and think it. Close your hand and think properly: "Now I cannot open it". Try! (she cannot), you see that your will is not much good to you.

Observation.—This is the essential point of the method. In order to make auto-suggestions, you must eliminate the *will* completely and only address yourself to the *imagination,* so as to avoid a conflict between them in which the will would be vanquished.

To become stronger as one becomes older seems paradoxical, but it is true.

For diabetes: "Continue to use therapeutic treatments; I am quite willing to make suggestions to you, but I cannot promise to cure you.

Observation.—I have seen diabetes completely cured several times, and what is still more extraordinary, the albumen diminish and even disappear from the urine of certain patients.

This obsession must be a real nightmare. The people you used to detest are becoming your friends, you like them and they like you.

Ah, but to *will* and to *desire* is not the *same* thing.

Then, after having asked them to close their eyes, M. Coué gives to his patients the little suggestive discourse which is to be found in "Self Mastery". When this is over, he again addresses himself to each one separately, saying to each a few words on his case:

To the first: "You, Monsieur, are in pain, but I tell you that, from to-day, the cause of this pain whether it is called arthritis or anything else, is going to disappear with the help of your unconscious, and the cause having disappeared, the pain will gradually become less and less, and in a short time it will be nothing but a moment."

To the second person: "Your stomach does not function properly, it is more or less dilated. Well, as I told you just now, your digestive functions are going to work better and better, and I add that the dilatation of the stomach is going to disappear little by little. Your organism is going to give back progressively to your stomach the force and elasticity it had lost, and by degrees as this phenomenon is produced, the stomach will return to its primitive form and will carry out more and more easily the necessary movements to pass into the intestine the nourishment it contains. At the same time the pouch formed by the relaxed stomach will diminish in size, the nutriment will no longer stagnate in this pouch, and in consequence the fermentation set up will end by totally disappearing.

To the third: To you, Mademoiselle, I say that whatever lesions you may have in your liver, your organism is doing what is necessary to make these lesions, disappear every day, and by degrees as they heal over, the symptoms from which you suffer will go on lessening and disappearing. Your liver then functions in a more and more normal way, the bile it secretes is alcaline and no longer acid, in the right quantity and quality, so that it passes naturally into the intestines and helps intestinal digestion.

To the fourth: My child, you hear what I say; every time you feel you are going to have an attack, you will hear my voice telling you as quick as lightning: "No, no!

my friend, you are not going to have that attack, and it is going to disappear before it comes..."

To the fifth, etc., etc.

When everyone has been attended to, M. Coué tells those present to open their eyes, and adds: "You have heard the advice I have just given you. Well, to transform it into reality, what you must do is this: *As long as you live,* every morning before getting up, and every evening as soon as you are in bed, you must shut your eyes, so as to concentrate your attention, and repeat twenty times following, moving your *lips* (that is indispensable) and counting *mechanically* on a string with twenty knots in it the following phrase: *"Every day, in every respect, I am getting better and better".*

There is no need to think of anything in particular, as the words *"in every respect"* apply to everything. This auto-suggestion must be made with confidence, with faith, with the certainty of obtaining what is desired. The greater the conviction of the person, the greater and the more rapid will be the results obtained.

Further, every time that in the course of the day or night you feel any physical or mental discomfort, *affirm* to yourself that you will not consciously contribute to it, and that you are going to make it vanish; then isolate yourself as much as possible, and passing your hand over your forehead if it is something mental, or on whatever part that is painful if it is something physical, repeat *very quickly,* moving the lips, the words: "It is going, it is going..., etc., etc." as long as it is necessary. With a little practice, the mental or physical discomfort will disappear in about 20 to 25 seconds. Begin again every time it is necessary.

For this as for the other autosuggestions it is necessary to act with the same confidence, the same conviction, the same faith, and above all without effort".

M. Coué also adds what follows: "If you formerly allowed yourself to make bad autosuggestions because you did it unconsciously, now that you know what I have just

taught you, you must no longer let this happen. And if, in spite of all, you still do it, you must only accuse yourself, and say *"Mea culpa, mea maxima culpa"*.

And now, if a grateful admirer of the work and of the founder of the method may be allowed to say a few words, I will say. "Monsieur Coué shows us luminously that the power to get health and happiness is within us: we have indeed received this gift".

Therefore, suppressing, first of all, every cause of suffering *created or encouraged by ourselves,* then putting into practice the favourite maxim of Socrates: "Know thyself", and the advice of Pope: "That I may reject none of the benefits that Thy goodness bestows upon me", let us take possession of the entire benefit of autosuggestion, let us become this very day members of the "Lorraine Society of applied Psychology"; let us make members of it those who may be in our care (it is a good deed to do to them).

By this means we shall follow first of all the great movement of the future of which M. E. Coué is the originator (he devotes to it his days, his nights, his worldly goods, and refuses to accept... but hush! no more of this! lest his modesty refuses to allow these lines to be published without alteration), but above all by this means we shall know exactly the days and hours of his lectures at Paris, Nancy and other towns, where he devotedly goes to sow the good seed, and where we can go too to see him, and hear him and consult him personally, and with his help awake or stir up in ourselves the personal power that everyone of us has received of becoming happy and well.

May I be allowed to add that when M. Coué has charged an entrance fee for his lectures, they have brought in thousands of francs for the Disabled and others who have suffered through the war.

E. Vs... oer.

Note.—Entrance is free to the members of the Lorraine Society of applied Psychology.

SOME NOTES ON THE JOURNEY OF M. COUÉ TO PARIS IN OCTOBER, 1919

The desire that the teachings of M. Coué in Paris last October should not be lost to others, has urged me to write them down. Putting aside this time the numerous people, physically or mentally ill, who have seen their troubles lessen and disappear as the result of his beneficent treatment, let us begin by quoting just a few of his teachings.

Question.—Why is it that I do not obtain better results although I use your method and prayer?

Answer.—Because, probably, at the back of your mind there is an *unconscious doubt*, or because you make *efforts*. Now, remember that efforts are determined by the will; if you bring the will into play, you run a serious risk of bringing the imagination into play too, but in the contrary direction, which brings about just the reverse of what you desire.

Question.—What are we to do when something troubles us?

Answer.—When something happens that troubles you, *repeat* at once "No, that does not trouble me at all, not in the least, the fact is rather agreeable than otherwise." In short, the idea is to work ourselves up in a good sense instead of in a bad.

Question.—Are the preliminary experiments indispensable if they are unacceptable to the pride of the subject?

Answer.—No, they are not indispensable, but they are of great utility; for although they may seem childish to certain people, they are on the contrary extremely serious; they do indeed prove three things:

1. That every idea that we have in our minds becomes

true for us, and has a tendency to transform itself into action.

2. That when there is a conflict between the imagination and the will, it is always the imagination which wins; and in this case we do exactly the *contrary* of what we wish to do.

3. That it is easy for us to put into our minds, *without any effort*, the idea that we wish to have, since we have been able without effort to think in succession: "I cannot", and then "I can".

The preliminary experiments should not be repeated at home; alone, one is often unable to put oneself in the right physical and mental conditions, there is a risk of failure, and in this case one's self-confidence is shaken.

Question.—When one is in pain, one cannot help thinking of one's trouble.

Answer.—Do not be afraid to think of it; on the contrary, do think of it, but to say to it. "I am not *afraid* of you".

If you go anywhere and a dog rushes at you barking, look it firmly in the eyes and it will not bite you; but if you fear it, if you turn back, he will soon have his teeth in your legs.

Question.—And if one does a retreat?

Answer.—Go backwards.

Question.—How can we realize what we desire?

Answer.—By often repeating what you desire: "I am gaining assurance", and you will do so; "My memory is improving", and it really does so; "I am becoming absolutely master of myself", and you find that you are becoming so.

If you say the contrary, it is the contrary which will come about.

What you say persistently and very quickly *comes to pass* (within the domain of the reasonable, of course).

Some testimonies:

A young lady to another lady: "How simple it is! There

is nothing to add to it: he seems inspired. Do you not think that there are beings who radiate influence?

... An eminent Parisian doctor to numerous doctors surrounding him: "I have entirely come over to the ideas of M. Coué".

... A Polytechnician, a severe critic, thus defines M. Coué: "He is a Power".

...Yes, he is a Power of Goodness. Without mercy for the bad autosuggestions of the "defeatist" type, but indefatigably painstaking, active and smiling, to help everyone to develop their personality, and to teach them to cure themselves, which is the characteristic of his beneficient method.

How could one fail to desire from the depths of one's heart that all might understand and seize the "good news" that M. Coué brings? "It is the awakening, possible for everyone, of the personal power which he has *received* of being happy and well."

It is, *if one consents,* the full development of this power which can transform one's life.

Then, and is it not quite rightly so? it is the strict duty (and at the same time the happiness) of those who have been intiated, to spread by every possible means the knowledge of this wonderful method, the happy results of which have been recognized and verified by *thousands* of persons, to make it known to those who suffer, who are sad, or who are overburdened... to all! and to help them to put it into practice.

Then, thinking of France, triumphant but bruised, of her defenders victorious but mutilated, of all the physical and moral suffering entailed by the war: may those who have the power (the greatest power ever given to man is the power of doing good [Socrates]) see that the inexhaustible reservoir of physical and moral forces that the "Method" puts within our reach may soon become the patrimony of all the nation and through it of humanity.

Mme. Emile Leon,
Collaborator, in Paris, of M. Emile Coué.

EXTRACTS FROM LETTERS ADDRESSED TO M. COUÉ

The final results of the English secondary Certificate have only been posted up these two hours, and I hasten to tell you about it, at least in so far as it concerns myself. I passed the viva voce *with flying colours,* and scarcely felt a trace of the nervousness which used to cause me such an intolerable sensation of nausea before the tests. During the latter I was astonished at my own calm, which gave those who listened to me the impression of perfect self-possession on my part. In short, it was just the tests I dreaded most which contributed most to my success. The jury placed me Second, and I am infinitely grateful to you for help, which undoubtedly gave me an advantage over the other candidates..., etc. (The case is that of a young lady who, on account of excessive nervousness, had failed in 1915. The nervousness having vanished under the influence of autosuggestion, she passed successfully, being placed 2nd out of more than 200 competitors.)

Mlle V...,
Schoolmistress, August 1916.

It is with very great pleasure that I write to thank you most sincerely for the great benefit I have received from your method. Before I went to you I had the greatest difficulty in walking 100 yards, without being out of breath, whereas now I can go miles without fatigue. Several times a day and quite easily, I am able to walk in 40 minutes from the rue du Bord-de-l'Eau to the rue des Glacis, that is to say, nearly four kilometres. The asthma from which I suffered has almost entirely disappeared.

Yours most gratefully.

Paul CHENOT,
Rue de Strasbourg, 141 *Nancy, Aug.* 1917.

I do not know how to thank you. Thanks to you I can say that I am almost entirely cured, and I was only waiting to be so in order to express my gratitude. I was suffering from two varicose ulcers, one on each foot. That on the right foot, which was *as big as my hand,* is entirely *cured* It seemed to disappear by magic. For weeks I had been confined to my bed, but almost immediately after I received your letter the ulcer healed over so that I could get up. That on the left foot is not yet absolutely healed, but will soon be so. Night and morning I do, and always shall, recite the prescribed formula, in which I have entire confidence. I may say also that my legs were as hard as a stone and I could not bear the slightest touch. Now I can press them without the least pain, and I can walk once more, which is the greatest joy.

Mme. Ligny,
Mailleroncourt-Charette (*Haute Saône*),
May 1918.

N. B.—It is worthy of remark that this lady never saw M. Coué, and that it is only thanks to a letter he wrote her on April 15th, that she obtained the result announced in her letter of May 3rd.

*
* *

I am writing to express my gratitude, for thanks to you I have escaped the risk of an operation which is always a very dangerous one. I can say more: you have saved my life, for your method of auto suggestion has done alone what all the medicines and treatments ordered for the terrible intestinal obstruction from which I suffered for 19 days, had failed to do. From the moment when I followed your instructions and applied your excellent principles, my functions have accomplished themselves quite naturally.

Mme S...,
Pont â Mousson, Feb. 1920.

I do not know how to thank you for my happiness in being cured. For more than 15 years I had suffered from attacks of asthma, which caused the most painful suffocations every night. Thanks to your splendid method, and above all, since I was present at one of your sèances, the attacks have disappeared as if by magic. It is a real miracle, for the various doctors who attended me all declared that there was no cure for asthma.

Mme V...,
Saint-Dié, Feb. 1920.

*
* *

I am writing to thank you with all my heart for having brought to my knowledge, a new therapeutic method, a marvellous instrument which seems to act like the magic wand of a fairy, since, thanks to the simplest means, it brings about the most extraordinary results. From the first I was extremely interested in your experiments, and after my own personal successes with your method, I began ardently to apply it, as I have become an enthusiastic supporter of it.

Docteur VACHET,
Vincennes, May 1920.

*
* *

For 8 years I have suffered from prolapse of the uterus. I have used your method of autosuggestion for the last five months, and am now completely cured, for which I do not know how to thank you enough.

Mme SOULIER,
Place du Marchè Toul, May 1920.

*
* *

I have suffered terribly for 11 years without respite. Every night I had attacks of asthma, and suffered also from insomnia and general weakness which prevented any occupation. Mentally, I was depressed, restless, worried, and

was inclined to make mountains out of mole hills. I had followed many treatments without success, having even undergone in Switzerland the removal of the turbinate bone of the nose without obtaining any relief. In Nov. 1918 I became worse in consequence of a great sorrow. While my husband was at Corfu (he was an officer on a warship), I lost our only son in six days from influenza. He was a delghtful child of ten, who was the joy of our life; alone and overwhelmed with sorrow, I reproached myself bitterly for not having been able to protect and save our treasure. I wanted to lose my reason or to die... When my husband returned (which was not until February), he took me to a new doctor who ordered me various remedies and the waters of Mont-Dore. I spent the month of August in that station, but on my return I had a recurrence of the asthma, and I realized with despair that *"in every respect"* I was getting worse and worse. It was then that I had the pleasure of meeting you. Without expecting much good from it. I must say, I went to your October lectures, and I am happy to tell you that by the end of November I was cured. Insomnia, feelings of oppression, gloomy thoughts, disappeared as though my magic, and I am now well and strong and full of courage. With physical health I have recovered my mental equilibrium, and but for the ineffaceable wound caused by my child's loss, I could say that I am perfectly happy. Why did I not meet you before? My child would have known a cheerful and courageous mother. Thank you again and again, M. Coué.

Yours most gratefully,

E. Itier,

Rue de Lille, Paris, April 1920.

*
* *

I can now take up again the struggle I have sustained for 30 years, and which had exhausted me.

I found in you last August a wonderful and providen-

tial help. Coming home to Lorraine for a few days, ill, and with my heart full of sorrow, I dreaded the shock which I should feel at the sight of the ruins and distress... and I went away comforted and in good health. I was at the end of my tether, and unfortunately I am not religious. I longed to find someone who could help me, and meeting you by chance at my cousin's house you gave me the very help I sought. I can now work in a new spirit, I suggest to my unconscious to re-establish my physical equilibrium, and I do not doubt that I shall regain my former good health. A very noticeable improvement has already shown itself, and you will better understand my gratitude when I tell you that, suffering from diabetes with a renal complication, I have had several attacks of glaucoma, but my eyes are now recovering their suppleness. Since then my sight has become almost normal, and my general health has much improved.

Mlle. Th——,
Professor at the Young Ladies' College at Ch..., Jan. 1920.

*
* *

I read my thesis with success, and was awarded the highest mark and the congratulations of the jury. Of all these "honours" a large share belongs to you, and I do not forget it. I only regretted that you were not present to hear your name referred to with warm and sympathetic interest by the distinguished Jury. You can consider that the doors of the University have been flung wide open to your teaching. Do not thank me for it, for I owe you far more than you can owe me.

Ch. Baudouin,
Professor at the Institut. J.-J. Rousseau, Geneva.

*
* *

... I admire your courageousness, and am quite sure that it will help to turn many friends into a useful and intelli-

gent direction. I confess that I have personally benefited by your teaching, and have made my patients do so too.

At the Nursing Home we try to apply your method collectively, and have already obtained visible results in this way.

Docteur BERILLON,
Paris, March, 1920.

*
* *

... I have received your kind letter as well as your very interesting lecture.

I am glad to see that you make a rational connection between hetero and autosuggestion, and I note particularly the passage in which you say that the will must not intervene in autosuggestion. That is what a great number of professors of autosuggestion, unfortunately including a large number of medical men, do not realize at all. I also think that an absolute distinction should be established between autosuggestion and the training of the will.

Docteur VAN VELSEN,
Brussels, March 1920.

*
* *

What must you think of me? That I have forgotten you? Oh, no, I assure you that I think of you with the most grateful affection, and I wish to repeat that your teachings are more and more efficacious; I never spend a day without using autosuggestion with increased success, and I bless you every day, for your method is the true one. Thanks to it, I am assimilating your excellent directions, and am able to control myself better every day, and I feel that I am *stronger*... I am sure that you would find it difficult to recognize in this woman, so active in spite of her 66 years, the poor creature who was so often ailing, and who only began to be well thanks to you and your guidance. May you be blessed for this, for the sweetest

thing in the world is to do good to those around us. You do much, and I do a little, for which I thank God.

Mme M...,
Cesson-Saint-Brieuc.

*
* *

As I am feeling better and better since I began to follow your method of autosuggestion, I should like to offer you my sincere thanks. The lesion in the lungs has disappeared, my heart is better. I have no more albumen, in short I am quite well.

Mme. LEMAITRE,
Richemont, June 1920.

*
* *

Your booklet and lecture interested us very much. It would be desirable for the good of humanity that they should be published in several languages, so that they might penetrate to every race and country, and thus reach a greater number of unfortunate people who suffer from the wrong use of that all-powerful (and almost divine) faculty, the most important to man, as you affirm and prove so luminously and judiciously, which we call the Imagination. I had already read many books on the will, and had quite an arsenal of formulae, thoughts, aphorisms, etc. Your phrases are conclusive. I do not think that ever before have "compressed tablets of self confidence". —as I call your healing phrases,—been condensed into typical formulae in such an intelligent manner.

Don Enrique C...,
Madrid.

*
* *

Your pamphlet on "the self-control" contains very strong arguments and very striking examples. I think that the substitution of imagination for the power of the will is a great progress. It is milder and more persuasive.

A. F., *Reimiremont.*

...I am happy to be able to tell you that my stomach is going on well. My metritis is also much better. My little boy had a gland in his thigh as big as an egg which is gradually disappearing.

E. L..., *Saint-Clément* (*M-et-M.*)

*
* *

After I had undergone three operations in my left leg on account of a local tuberculosis, that leg became ill again in September 1920. Several doctors declared that a new operation was necessary. They were about to open my leg from the knee to the ankle, and if the operation had failed, they would have had to perform an amputation.

As I had heard of your wondrous cures I came and saw you for the first time on the 6th of November 1920. After the sèance, I felt immediately a little better. I exactly followed your instructions and went three times to you. At the third time, I could tell you that I was completely cured.

Mme L..., *Henry* (*Lorraine*).

*
* *

... I will not wait any longer to thank you heartily for all the good I owe you. Autosuggestion has positively transformed me and I am now getting much better than I have been these many years. The symptoms of illness have disappeared little by little, the morbid symptoms have become rarer and rarer, and all the functions of the body work now normally. The result is that, after having become thinner and thinner during several years. I have regained several kilos in a few months.

I cannot do otherwise than bless the Coué system.

L..., *Cannes* (*A. M.*).

*
* *

Since 1917, my little girl has been suffering from epileptic crises. Several doctors had told me that about the

age of 14 or 15 they would disappear or become worse. Having heard of you, I sent her to you from the end of December till May. Now her cure is complete, for during six months she has had no relapse.

PERRIN (Charles),
Essey-les Nancy.

*
* *

For eight years, I had suffered from a sinking of the uterus. After having practised your autosuggestion for five months, I have been radically cured. I don't know how to express my deep gratitude.

Mme. SOULIE,
6, *Place du Marchè, Toul.*

* *
*

... Having suffered from a glaucoma since 1917, I have consulted two oculists who told me that only an operation would put an end to my sufferings, but unfortunately neither of them would assure me of a good result.

In the month of June 1920, after having attended one of your séances I felt much better. In September I ceased to use the drops of pilocarpine which were the daily bread of my eye, and since then I have felt no more pain. My pupil is no more dilated, my eyes are normal; it is a real miracle.

Mme. M..., *â Soulosse.*

*
* *

A dedication to M. Coué by the author of a medical treatise:

To M. Coué who knew how to dissect the human soul and to extract from it a psychologic method founded on conscious auto suggestion.

The master is entitled to the thanks of all; he has cleverly succeeded in disciplining the vagrant (Imagination) and in associating it usefully with the will.

Thus he has given man the means of increasing tenfold his moral force by giving him confidence in himself.

Docteur P. R., *Francfort.*

*
* *

... It is difficult to speak of the profound influence exercised on me by your so kindly allowing me to view so often your work. Seeing it day by day, as I have done, it has impressed me more and more, and as you yourself said, there seems no limits to the possibilities and future scope of the principles you enunciate, not only in the physical life of children but also in possibilities for changing the ideas now prevalent in punishment of crime, in government, in fact, in all the relations of life...

Miss Josephine M. Richardson.

*
* *

... When I came, I expected a great deal, but what I have seen, thanks to your great kindness, exceeds greatly my expectation.

Montagu S. Monier-Williams M. D.,
London.

FRAGMENTS FROM LETTERS

Addressed to Mme. EMILE LEON, Disciple of M. COUÉ

For some time I have been wanting to write and thank you most sincerely for having made known to me this method of auto-suggestion. Thanks to your good advice the attacks of nerves to which I was subject have entirely disappeared, and I am certain that I am quite cured. Further, I feel myself surrounded by a superior force which is an unfaltering guide, and by whose aid I surmount with ease the difficulties of life.

Mme F...,
Rue de Bougainville, 4, *Paris.*

*
* *

Amazed at the results obtained by the auto suggestion which you made known to me, I thank you with all my heart.

For a year I have been entirely cured of articular rheumatism of the right shoulder from which I had suffered for eight years, and from chronic bronchitis which I had had still longer. The numerous doctors I had consulted declared me incurable, but thanks to you and to your treatment, I have found with perfect health the conviction that I possess the power to keep it.

Mme L. T...,
Rue du Laos, 4, *Paris.*

*
* *

I want to tell you what excellent results M. Coué's wonderful method has produced in my case, and to express my deep gratitude for your valuable help. I have always been anaemic, and have had poor health, but after my husband's death I became much worse. I suffered with my

kidneys, I could not stand upright, I also suffered from nervousness and aversions. All that has gone and I am a different person. I no longer suffer, I have more endurance, and I am more cheerful. My friends hardly recognize me, and I feel a new woman. I intend to spread the news of this wonderful method, so clear, so simple, so beneficient, and to continue to get from it the best results for myself as well.

M. L. D..., *Paris, June* 1920.

*
* *

I cannot find words to thank you for teaching me your good method. What happiness you have brought to me! I thank God who led to make your acquaintance, for you have entirely transformed my life. Formerly I suffered terribly at each monthly period and was obliged to lie in bed. Now all is quite regular and painless. It is the same with my digestion, and I am no longer obliged to live on milk as I used, and I have no more pain, which is a joy. My husband is astonished to find that when I travel I have no more headaches, whereas before I was always taking tablets. Now, thanks to you, I need no remedies at all, but I do not forget to repeat 20 times morning and evening, the phrase you taught me: "Every day, in every respect, I am getting better and better".

B. P..., *Paris, October* 1920.

*
* *

In re-reading the method I find it more and more superior to all the developments inspired by it. It surpasses all that has been invented of so-called scientific systems, themselves based on the uncertain results of an uncertain science, which feels its way and deceives itself, and of which the means of observation are also fairly precarious in spite of what the learned say. M. Coué, on the other hand, suffices for everything, goes straight to the aim, attains it with certainty, and in freeing his patient, carries

generosity and knowledge to its hightest point, since he leaves to the patient himself the merit of this freedom, and the use of a marvellous power. No, really, there is nothing to alter in this method. It is as you so strikingly say: a Gospel. To report faithfully his acts and words and spread his method, that is what must be done, and what I shall do myself as far as is in any way possible.

P. C.

*

* *

I am amazed at the results that I have obtained and continue to obtain daily, by the use of the excellent method you have taught me of conscious auto suggestion. I was ill mentally and physically. Now I am well and am also nearly always cheerful. That is to say that my depression has given way to cheerfulness, and certainty I do not complain of the change, for it is very preferable, I assure you. How wretched I used to be! I could digest nothing; now I digest perfectly well and the intestines act naturally. I also used to sleep so badly, whereas now the nights are not long enough; I could not work, but now I am able to work hard. Of all my ailments nothing is left but an occasional touch of rheumatism, which I feel sure will disappear like the rest by continuing your good method. I cannot find words to express my deep gratitude to you.

Mme Friry,
Boulevard Malesherbes, Paris.

EXTRACTS FROM LETTERS

Addressed to Mlle. KAUFMANT, Disciple of M. COUÉ.

As I have been feeling better and better since following the method of autosuggestion which you taught me, I feel I owe you the sincerest thanks, I am now qualified to speak of the great and undeniable advantages of this method, as to it alone I owe my recovery. I had a lesion in the lungs which caused me to spit blood. I suffered from lack of appetite, daily vomiting, loss of flesh, and obstinate constipation. The spitting of blood lessened at once and soon entirely disappeared. The vomiting ceased, the constipation no longer exists, I have got back my appetite, and in two months I have gained nearly a stone in weight. In the face of such results observed, not only by parents and friends, but also by the doctor who has been attending me for several months, it is impossible to deny the good effect of autosuggestion and not to declare openly that it is to your method that I owe my return to life. I authorize you to publish my name if it is likely to be of service to others, and I beg you to believe me.

Yours most gratefully,

Jeanne GILLI,
15, *Av. Borriglione, Nice, March* 1918.

*
* *

I consider it a duty to tell you how grateful I am to you for acquainting me with the benefits of autosuggestion. Thanks to you, I no longer suffer from those agonizing and frequent heart stoppages, and I have regained my appetite which I had lost for months. Still more, as a hospital nurse, I must thank you from my heart for the almost miraculous recovery of one of my patients, seriously ill with tuberculosis, which caused him to vomit blood con-

stantly and copiously. His family and myself were very anxious when heaven sent you to him. After your first visit the spitting of blood ceased, his appetite returned, and after a few more visits made by you to his sick bed, all the organs little by little resumed their normal functions. At last one day we had the pleasant surprise and joy of seeing him arrive at your private séance, where, before those present, he himself made the declaration of his cure, due to your kind intervention.

Thank you with all my heart.

Yours gratefully and sympathetically,
A. KETTNER,
26, *Av. Borriglione, Nice, March* 1918.

*
* *

...From day to day I have put off writing to you to thank you for the cure of my little Sylvain. I was in despair, the doctors telling me that there was nothing more to be done but to try the sanatorium of Arcachon or Juicoot, near Dunkirk. I was going to do so when Mme Collard advised me to go and see you. I hesitated, as I felt sceptical about it; but I now have the proof of your skill, for Sylvain has completely recovered. His appetite is good, his pimples and his glands are completely cured, and what is still more extraordinary, since the first time that we went to see you he has not coughed any more, not even once; the result is, that since the month of June he has gained 6 lbs.; I can never thank you enough and I proclaim to everyone the benefits we have received.

Mme POIRSON,
Liverdun, August, 1920.

*
* *

How can I prove to you my deep gratitude? You have saved my life. I had a displaced heart, which caused terrible attacks of suffocation, which went on continually; in fact they were so violent that I had no rest day or night,

in spite of daily injections of morphia. I could eat nothing without instant vomiting. I had violent pains in the head which became all swollen, and as a result I lost my sight. I was in a lamentable state and my whole organism suffered from it. I had abscesses on the liver. The doctor despaired of me after having tried everything; blood letting, cupping and scarifying, poultices, ice, and every possible remedy, without any improvement. I had recourse to your kindness on the doctor's advice.

After your first visits the attacks became less violent and less frequent, and soon disappeared completely. The bad and troubled nights became calmer, until I was able to sleep the whole night through without waking. The pains I had had in the liver ceased completely. I could begin to take my food again, digesting it perfectly well, and I again experienced the feeling of hunger which I had not known for months. My headaches ceased, and my eyes, which had troubled me so much, are quite cured, since I am now able to occupy myself with a little manual work.

At each visit that you paid me, I felt that my organs were resuming their natural functions. I was not the only one to observe it, for the doctor who came to see me every week found me much better, and finally there came recovery, since I could get up after having been in bed eleven months. I got up without any discomfort, not even the least giddiness, and in a fortnight I could go out. It is indeed thanks to you that I am cured, for the doctor says that for all that the medicines did me, I might just as well have taken none.

After having been given up by two doctors who held out no hope of cure, here I am cured all the same, and it is indeed a complete cure, for now I can eat meat, and I eat a pound of bread every day. How can I thank you, for I repeat, it is thanks to the suggestion you taught me that I owe my life.

Jeanne GROSJEAN,
Nancy, Nov. 1920.

... Personally the science of auto suggestion,—for I consider it as entirely a *science,*—has rendered me great services; but truth compels me to declare that if I continue to interest myself particularly in it, it is because I find in it the means of exercising true charity.

In 1915 when I was present for the first time at M. Coué's lectures, I confess that I was entirely sceptical. Before facts a *hundred times* repeated in my presence, I was obliged to surrender to evidence, and recognize that auto suggestion always acted, though naturally in different degrees, on organic diseases. The only cases (and those were very rare) in which I have seen it fail are nervous cases, neurasthenia or imaginary illnesses.

There is no need to tell you again that M. Coué, like yourself, but even more strongly, insists on this point: "that he never performs a miracle or cures anybody, but that he shows people how to cure themselves". I confess that on this point I still remain a trifle incredulous, for if M. Coué does not actually cure people, he is a powerful aid to their recovery, in "giving heart" to the sick, in teaching them never to despair, in uplifting them, in leading them... higher than themselves into moral spheres that the majority of humanity, plunged in materialism, has never reached.

The more I study auto suggestion, the better I understand the divine law of confidence and love that Christ preached us: "Thou shalt love thy neighbor" and by giving a little of one's heart and of one's moral force to help him to rise if he has fallen and to cure himself if he is ill. Here also from my Christian point of view, is the application of autosuggestion which I consider as a beneficial and comforting science which helps us to understand that as the children of God, we all have within us forces whose existence we did not suspect, which properly directed, serve to elevate us morally and to heal us physically.

Those who do not know your science, or who only know

it imperfectly, should not judge it without having seen the results it gives and the good it does.

Believe me to be your faithful admirer,

M. L. D..., *Nancy, November* 1920.

"EVERYTHING FOR EVERYONE"

By Mme. Emil Leon, Disciple of M. Coué.

When one has been able to take advantage of a great benefit; when this benefit is within reach of everyone, although almost everyone is ignorant of it, is it not an urgent and absolute duty (for those who are initiated) to make it known to those around them? For all can make their own the amazing results of the "Emile Coué Method".

To drive away pain is much... but how much more is it to lead into the possession of a new life *all* those who suffer...

Last April we had the visit of M. Emile Coué at Paris, and here are some of his teachings:

Question.—Question of a theist: I think it is unworthy of the Eternal to make our obedience to his will, depend on what M. Coué calls a trick or mechanical process: conscious autosuggestion.

M. Coué.—Whether we wish it or not, our imagination always overrules our will, when they are in conflict. We can lead it into the right path indicated by our reason, by *consciously* employing the mechanical process that we employ *unconsciously* often to lead into the wrong.

And the thoughtful questioner says to herself: "Yes, it is true, in this elevated sphere of thought, conscious autosuggestion has the power to free us from obstacles *created by ourselves,* which might as it were put a veil between us and God, just as a piece of stuff, hanging in a window, can prevent the sun from coming into a room.

Question.—How ought one to set about bringing those dear to one who may be suffering, to make themselves good autosuggestions which would set them free?

Answer.—Do not insist or lecture them about it. Just

remind them simply that I advise them to make an auto-suggestion with the *conviction* that they will obtain the result they want.

Question.—How is one to explain to oneself and to explain to others that the repetition of the same words: "I am going to sleep... It is going away..." etc., has the power to produce the effect, and above all so powerful an effect that it is a certain one?

Answer.—The repetition of the same words forces one to think them, and when we think them they become true for us and transform themselves into reality.

Question.—How is one to keep inwardly the mastery of oneself?

Answer.—To be master of oneself it is enough to think that one is so, and in order to think it, one should often repeat it without making any effort.

Question.—And outwardly, how is one to keep one's liberty?

Answer.—Self mastery applies just as much physically as mentally.

Question (Affirmation).—It is impossible to escape trouble or sadness, if we do not do as we should, it would not be just, and autosuggestion, cannot... and ought not to prevent *just suffering.*

M. Coué (very seriously and affirmatively).—Certainly and assuredly it ought not to be so, but it is so often... at any rate for a time.

Question.—Why did that patient who has been entirely cured, continually have those terrible attacks?

Answer.—He expected his attacks, he feared them... and so he *provoked* them; if this gentleman gets well into his mind the idea that he will have no more attacks, he will not have any; if he thinks that he will have them, he will indeed do so.

Question.—In what does your method differ from others

Answer.—The difference in my method is: that it is

not the *will* which rules us but the *imagination;* that is the basis, the fundamental basis.

Question.—Will you give me a summary of your "Method" for Mme R... who is doing an important work?

M. E. Coué.—Here is the summary of the "Method" in a few words: Contrary to what is taught, it is not our will which makes us act, but our imagination (the unconscious). If we often do act as we *will,* it is because at the same time we think that we can. If it is not so, we do exactly the reverse of what we wish. Ex: The more a person with insomnia *determines* to sleep, the more excited she becomes; the more we *try* to remember a name which we think we have forgotten, the more it escapes us (it comes back only if, in your mind, you replace the idea: "I have forgotten", by the idea "it will come back"); the more we strive to prevent ourselves from laughing, the more our laughter bursts out; the more we *determine* to avoid an obstacle, when learning to bicycle, the more we rush upon it.

We must then apply ourselves to directing our *imagination* which now directs us; in this way we easily arrive at becoming masters of ourselves physically and morally.

How are we to arrive at this result? By the practice of conscious *autosuggestion.*

Conscious autosuggestion is based on this principle. Every idea that we have in our mind becomes true for us and tends to realize itself.

Thus, if we *desire* something, we can obtain it at the end of a more or less long time, if we often repeat that this thing is going to come, or to disappear, according to whether it is a good quality or a fault, either physical or mental.

Everything is included by employing night and morning the general formula: "Every day, *in every respect,* I am getting better and better".

Question.—For those who are sad—who are in distress?

Answer.—As long as you think: "I am sad", you *cannot* be cheerful, and in order to think something, it is

enough to say without effort: "I do think this thing—"; as to the distress it will disappear, however violent it may be, *that* I *can* affirm.

A man arrives bent, dragging himself painfully along, leaning on two sticks; he has on his face an expression of dull depression. As the hall is filling up, M. E. Coué enters. After having questioned this man, he says to him something like this: "So you have had rheumatism for 32 years and you cannot walk. Don't be afraid, it's not going to last as long as that again".

Then after the preliminary experiments: "Shut your eyes, and repeat very quickly indeed, moving your lips, the words: "It is going, it is going" (at the same time M. Coué passes his hand over the legs of the patient, for 20 to 25 seconds). Now you are no longer in pain, get up and walk (the patient walks) quickly! quicker! more quickly still! and since you can walk so well, you are going to run; run! Monsieur, run! The patient runs (joyously, almost as if he had recovered his youth), to his great astonishment, and also to that of the numerous persons present at the séance of April 27th, 1920. (Clinic of Dr. Bérillon.)

A lady declares: "My husband suffered from attacks of asthma for many years, he had such difficulty in breathing that we feared a fatal issue; his medical adviser, Dr. X—— had given him up. He was almost radically cured of his attacks, after only one visit from M. Coué".

A young woman comes to thank M. Coué with lively gratitude. Her doctor, Dr. Vachet, who was with her in the room, says that the cerebral anæmia from which she had suffered for a long while, which he had not succeeded in checking by the usual means, had disappeared as if by magic through the use of conscious autosuggestion.

Another person who had had a fractured leg and could not walk without pain and limping, could at once walk normally. No more pain, no more limping.

In the hall which thrills with interest, joyful testimonies break out from numerous persons who have been relieved or cured.

A doctor: "Autosuggestion is the weapon of healing". As to this philosopher who writes (he mentions his name), he relies on the *genius* of Coué.

A gentleman, a former magistrate, whom a lady had asked to express his appreciation, exclaims in a moved tone: "I cannot put my appreciation into words— I think it is admirable—" A woman of the world, excited by the disappearance of her sufferings: "Oh, M. Coué, one could kneel to you— You are the merciful God!" Another lady, very much impressed herself, rectifies: "No, his messenger".

An aged lady: It is delightful, when one is aged and fragile, to replace a feeling of general ill health by that of refreshment and general well-being, and M. E. Coué's method can, I affirm for I have proved it, produce this happy result, which is all the more complete and lasting since it relies on the all-powerful force which is within us.

A warmly sympathetic voice calls him the modest name he prefers to that of "Master": Professor Coué.

A young woman who has been entirely won over: "M. Coué goes straight to his aim, attains it with sureness, and, in setting free his patient, carries generosity and knowledge to its highest point, since he leaves to the patient himself the merit of his liberation and the use of a marvellous power".

A literary man, whom a lady asks to write a little *"chef d'oeuvre"* on the beneficent "Method" refuses absolutely, emphasizing the simple words which, used according to the Method, help to make all suffering disappear: IT IS GOING AWAY— *that* is the *chef-d-oeuvre"* he affirms.

And the thousands of sick folks who have been relieved or cured will not contradict him.

A lady who has suffered much declares: "In re-reading the "Method" I find it more and more superior to the developments it has inspired; there is really nothing to take away nor add to this "Method"—all that is left is to spread it. I shall do so in every possible way".

And now in conclusion I will say: Although M. Coué's modesty makes him reply to everyone:

I have no magnetic fluid—

I have no influence—

I have never cured anybody—

My disciples obtain the same results as myself—

"I can say in all sincerity that they tend to do so, instructed as they are in the *valuable "Method"*, and when, in some far distant future, the thrilling voice of its author called to a higher sphere can no longer teach it here below, the "Method", his work, will help in aiding, comforting, and curing thousands and thousands of human beings: it must be *immortal*, and communicated to the entire world by generous France— for the man of letters was right, and knew how to illuminate in a word this true simple, and marvellous help in conquering pain: "IT IS GOING AWAY—! *There is the chef-d'oeuvre!"*

B. K. (Emile-Leon).

Paris, June 6th, 1920.

EDUCATION AS IT OUGHT TO BE

It may seem paradoxical but, nevertheless, the Education of a child ought to begin before its birth.

In sober truth, if a woman, a few weks after conception, makes a mental picture of the sex of the child she is going to bring forth into the world, of the physical and moral qualities with which she desires to see it endued and if she will continue during the time of gestation to impress on herself the same mental image, the child will have the sex and qualities desired.

Spartan women only brought forth robust children, who grew to be redoubtable warriors, because their strongest desire was to give such heroes to their country; whilst, at Athens, mothers had intellectual children whose mental qualities were a hundredfold greater than their physical attributes.

The child thus engendered will be apt to accept readily good suggestions which may be made to him and to transform them into autosuggestions which later, will influence the course of his life. For you must know that all our words, all our acts, are only the result of autosuggestions caused, for the most part, by the suggestion of example or speech.

How then should parents, and those entrusted with the education of children avoid provoking bad autosuggestions and, on the other hand, influence good autosuggestions?

In dealing with children, always be even-tempered and speak in a gentle but firm tone. In this way they will become obedient without ever having the slightest desire to resist authority.

Above all—above all, avoid harshness and brutality, for there the risk is incurred of influencing an autosuggestion of cruelty accompanied by hate.

Moreover, avoid carefully, in their presence, saying evil

of anyone, as too often happens, when, without any deliberate intention, the absent nurse is picked to pieces in the drawing-room.

Inevitably this fatal example will be followed, and may produce later a real catastrophe.

Awaken in them a desire to know the reason of things and a love of Nature, and endeavor to interest them by giving all possible explanations very clearly, in a cheerful, good-tempered tone. You must answer their questions pleasantly, instead of checking them with—"What a bother you are, do be quiet, you will learn that later".

Never on any account say to a child, "You are lazy and good for nothing" because that gives birth in him to the very faults of which you accuse him.

If a child is lazy and does his tasks badly, you should say to him one day, even if it is not true, "There this time your work is much better than it generally is. Well done". The child, flattered by the unaccustomed commendation, will certainly work better the next time, and, little by little, thanks to judicious encouragement, will succeed in becoming a real worker.

At all costs avoid speaking of illness before children, as it will certainly create in them bad autosuggestions. Teach them, on the contrary, that health is the normal state of man, and that sickness is an anomaly, a sort of backsliding which may be avoided by living in a temperate, regular way.

Do not create defects in them by teaching them to fear this or that, cold or heat, rain or wind, etc. Man is created to endure such variations without injury and should do so without grumbling.

Do not make the child nervous by filling his mind with stories of hob-goblins and were-wolves, for there is always the risk that timidity contracted in childhood will persist later.

It is necessary that those who do not bring up their children themselves should choose carefully those to whom they are entrusted. To love them is not sufficient, they

must have the qualities you desire your children to possess.

Awaken in them the love of work and of study, making it easier by explaining things carefully and in a pleasant fashion, and by introducing in the explanation some anecdote which will make the child eager for the following lesson.

Above all impress on them that Work is essential for man, and that he who does not work in some fashion or another, is a worthless, useless creature, and that all work produces in the man who engages in it a healthy and profound satisfaction; whilst idleness, so longed for and desired by some, produces weariness, neurasthenia, disgust of life, and leads those who do not possess the means of satisfying the passions created by idleness, to debauchery and even to crime.

Teach children to be always polite and kind to all, and particularly to those whom the chance of birth has placed in a lower class than their own, and also to respect age, and never to mock at the physical or moral defects that age often produces.

Teach them to love all mankind, without distinction of caste. That one must always be ready to succor those who are in need of help, and that one must never be afraid of spending time and money for those who are in need; in short, that they must think more of others than of themselves.

In so doing an inner satisfaction is experienced that the egoist ever seeks and never finds.

Develop in them self-confidence, and teach that, before embarking upon any undertaking, it should be submitted to the control of reason, thus avoiding acting impulsively, and, after having reasoned the matter out, one should form a decision by which one abides, unless, indeed, some fresh fact proves you may have been mistaken.

Teach them above all that every one must set out in life with a very definite idea that he will succeed, and that, under the influence of this idea he will inevitably succeed. Not indeed, that he should quietly remain expecting events

to happen, but because, impelled by this idea, he will do what is necesary to make it come true.

He will know how to take advantage of opportunities, or even perhaps of the single opportunity which may present itself, it may be only a single thread or hair, whilst he who distrusts himself is a Constant Guignard with whom nothing succeeds, because his efforts are all directed to that end.

Such a one may indeed swim in an ocean of opportunities, provided with heads of hair like Absalom himself, and he will be unable to seize a single hair, and often determines himself the causes which make him fail; whilst he, who has the idea of success in himself, often gives birth, in an unconscious fashion, to the very circumstances which produce that same success.

But above all, let parents and masters preach by example. A child is extremely suggestive, let something turn up that he wishes to do, and he does it.

As soon as children can speak, make them repeat morning and evening, twenty times consecutively:

"Day by day, in all respects, I grow better", which will produce in them an excellent physical, moral and healthy atmosphere.

If you make the following suggestion you will help the child enormously to eliminate his faults, and to awaken in him the corresponding desirable qualities.

Every night when the child is asleep, approach quietly, so as not to awaken him, to within about three or four feet from his bed. Stand there, murmuring in a low monotonous voice the thing or things you wish him to do.

Finally, it is desirable that all teachers should, every morning, make suggestions to their pupils, somewhat in the following fashion.

Telling them to shut their eyes, they should say; "Children, I expect you always to be polite and kind to everyone, obedient to your parents and teachers, when they give you an order, or tell you anything; you will always listen to the order given or the fact told without thinking it

tiresome; you used to think it tiresome when you were reminded of anything, but now you understand very well that it is for your good that you are told things, and consequently, instead of being cross with those who speak to you will now be grateful to them.

"Moreover you will now love your work, whatever it may be; in your lessons you will always enjoy those things you may have to learn, especially whatever you may not till now have cared for.

"Moreover when the teacher is giving a lesson in class, you will now devote all your attention, solely and entirely to what he says, instead of attending to any silly things said or done by your companions, and without doing or saying anything silly yourself.

"Under these conditions as you are all intelligent, for, children, you are all intelligent, you will understand easily and remember easily what you have learned. It will remain embedded in your memory, ready to be at your service, and you will be able to make use of it as soon as you need it.

"In the same way when you are working at your lessons alone, or at home, when you are accomplishing a task or studying a lesson, you will fix your attention solely on the work you are doing, and you will always obtain good marks for your lessons."

This is the Counsel, which, if followed faithfully and truly from henceforth, will produce a race endued with the highest physical and moral qualities.

Emil Coué.

FORM OF APPLICATION FOR MEMBERSHIP

IN THE

Lorraine Society of Applied Psychology

Headquarters: at M. COUÉ'S,
rue Jeanne-d'Arc, 186, Nancy, France

OUR AIM

The aim of the Society is the study of the phenomena due to suggestion and hypnotism properly so-called, and the possible applications of these phenomena to training, re-training, the cure of illnesses, etc.

The composition of the Society is as follows:

1. HONORARY MEMBERS;
2. ASSOCIATES: Yearly subscription: 10 FRANCS;
3. ORDINARY MEMBERS: Yearly subscription: 5 FRANCS.

I beg to enclose the sum of.....

in order to become Associate / Member or of the L. S. A. P.,

and to receive the publications and to have free right of entrance into the lectures organized by it.

PREFACE

THE influence of the mind in the causation and in the cure of disease has been exaggerated in general literature and many so-called scientific writings, but it is real and must be recognized. Had physicians given more thought to psychic treatment there would to-day be no cause for complaint in regard to the increasing harm which is being done by ignorant enthusiasts and wilful impostors.

I have endeavored in the present work to present scientific facts impartially and to submit them to a fair analysis; only after such treatment have I given what seems to me to be the inevitable conclusion. Some such guide to correct reasoning in the intricate subject of suggestion and psychotherapy is needed. Every person who has not had a scientific, I might say a laboratory, training is prone instinctively—at any rate unless he uses reflection—to confound two very different things, that which he really perceives and his deduction from what he

has seen, felt, or heard. I trust this book will show the fallacy of confounding facts with opinions.

It is very possible that I have not succeeded throughout in expressing myself in as simple terms as might be desired; if this is so I must ask the reader's forbearance. While I have started from elementary facts and from them have proceeded to more complicated ideas, I have nevertheless been obliged to accredit my readers with a certain degree of general scientific culture. Such readers certainly will not hesitate to reread any chapter which at first may to them seem obscure.

The book, being systematically written, can be studied profitably only as a whole; it would be unfair to reader or writer to consider single chapters separate from their sequential context, for each follows logically upon the other and every succeeding page is dependent upon what has gone before. This must be borne in mind also in relation to technical expressions, for terms used later in the work may seem obscure to those who have not read the short definitions given when the technical designation was employed for the first time. Nor is it essential that every reader should understand all of the contents of the entire book. If each gathers

but a single kernel of truth and widens his point of view by the acquisition of but a bit of knowledge the book will have been worth while.

Not long ago while sitting in a New York subway local train we were passed by an express going in the same direction. For a moment it seemed as though the local had come to a stop; then it appeared to reverse its course and go backward. The illusion was complete, yet I knew I was laboring under a sense deception and that both trains were going in one and the same direction. So, in this present time of progress and enlightenment, it may often appear as though the large masses of people were being carried along by ignorance and superstition, while true mental culture stands still or even goes backward. Yet this also would be an illusion, a sense deception, for scientific truth creeps forward slowly, but always steadily, and its ultimate conquest over mysticism and other occult enemies is assured.

CONTENTS

INTRODUCTION 3

Popularization of science in general—Popularization of medicine in particular—The good and the bad in popular instruction—Dangers of lay treatment—Benefits of popularized psychotherapy—Outline of the work.

PART FIRST: SUGGESTION

I. PSYCHOLOGICAL GROUNDWORK

A. PSYCHOLOGY AS A NATURAL SCIENCE . . 17

Speculative psychology—Empiric psychology—Objects of mind study—Exclusion of prejudice in investigation.

B. THE ORGANS OF MENTAL ACTIVITY . . . 20

The nerve formations—Stimulus and reaction—Differentiation of conduction tracts—Reflex phenomena—Sensory apparatus—Specific sensory energy—Nerve cells—The neuron—Sensory and motor nerves—The brain—Significance of weight and fissures—The brain cortex as the seat of the higher psychic functions—Localization of psychic functions—Results of embryological studies—Association centres—Transmission of sensory impressions—Gray and white matter—The spinal cord.

C. Contents and Course of Mental Activity 39

Sensory perceptions the basis of ideational life—Involuntary expressional movements—Stimulation confines—Sound and light perception—"After images"—Secondary sensory impressions—Memory images—Pictures of the imagination—"Passable" connecting tracts—Sleep-walking—Other elements of association of ideas—Psycho-physical parallelism—Graphic methods—Concepts—Law of similarity and simultaneity—Emotional tones—The will—Apperception and attention—The feeling of self—Speech—Freedom of the will.

D. Peculiarities of Mental Activity . . 75

Telepathy—Other "occult" phenomena—One-sidedness of genius—Sleep and dreams—Freud's dream analysis—Mind of the child—Development of association tracts—Muscular exercise—Development of the faculty of speech—Individual peculiarities of the male and the female mind—Difference of brain organization—Opinions of experts.

E. Disordered Mental Activity 105

Psychoses—Boundary between health and disease—False ideas and mental disease—Delusions which cannot be corrected—Sensory deceptions—Power of the imagination—Organic and functional nervous disorder.

II. SUGGESTION AS A PSYCHIC FORCE

A. Possibility and Nature of Suggestion . 131

Definition—Psychic infection—Adoption of a suggestion—Limits of suggestion—Reconstructed personality—Double personality—Ideational diseases—Dissociation of personality—Potency of a suggestion—Receptivity of weak characters.

B. Scope of Suggestion 147

Possibilities of suggestion—Organic changes cannot be produced by it—Alterations of function through suggestion—Views of the Nancy school—Suggestion not irresistible—Responsibility of hypnotized persons—Apparent death of Yogis.

C. Forms of Suggestion 163

Hypnosis and waking suggestion—Hypnosis not sleep—Verbal suggestion ample—Subconscious manifestations—Theory of dual personality—Subconsciousness is co-consciousness—Natural explanation of trance phenomena—Auto-suggestion, involuntary and purposeful—Foreign suggestion.

D. Suggestion—Its Past and Present . . 182

Wolf and dog madness in olden times—Flagellantism—Children's crusades and dance madness in the Middle Ages—The devil as the producer of functional nervous disorder—Temple sleep as a remedial agency—Mesmer and magnetism—Faria—Braid—Liébault—More recent investigators—Miracles and nature's laws—Modern superstition—Dukhobortsi and Raskolniks.

PART SECOND: PSYCHOTHERAPY

I. GENERAL CONSIDERATIONS

A. Definitions 209

Cure of the mind—Cure through the mind—Difference between psychotherapy and psychiatry—Secondary aim of psychotherapy.

B. The Justifiability of Psychotherapy . 211

Darwin's theory of the survival of the fittest—Alteration of natural conditions of life—Adaptation to conditions of civilization—The sick and the feeble as factors in civilization—Detriments to civilization and aim of combating them—Critical remarks on disease and human fault—The folly of belief in miracles—Medical science in the service of adaptation—Arguments against psychotherapy—Their fallacy—Psychotherapy in harmony with laws of nature.

C. Dangers of Psychotherapy 229

Special knowledge requisite—Importance of diagnosis—Charlatans grope in the dark—Injury to health through error of treatment—Dangers of experimentation—How to avoid them.

D. Christian Science, Faith and Prayer Cures 235

Superstition in medicine—The excuse for it in ancient times—Miracle reports of the priests—Adoration of relics and saints—Natural causes of "supernatural" cures—The comedy of mysticism—Mrs. Eddy, John Alexander Dowie, and Emmanuel movement—Disturbance of the unison with God as a cause of disease—Restoration of this unison as a means of treatment—The self-deception of faith and prayer healers.

E. The Personality of the Physician . . 262

Not the remedy but the physician cures—Essential attributes of the psychotherapist—Psychotherapeutic training—Knowledge of humanity and human conduct—Emotional qualities.

F. The Personality of the Patient . . . 270

Those most easily influenced—Insanities cannot be benefited—Psychotherapy addressed to personalities—Indirect influence on organic changes—Importance of individualization—Suggestibility of men, women, and children—The opposition of sceptics—Adaptation to the individuality an essential to psychotherapeutic success.

II. SPECIAL APPLICATION OF PSYCHOTHERAPY

A. The Most Important Methods . . . 282

1. Mental Therapeutics

Suggestion method—Catharsis—Freud's psycho-analysis—Determination of the cause of functional nervous disorders—Subsequent discharge of repressed emotions—Persistence of suppressed emotions in subconsciousness—Their reawakening in hypnosis—Memory exploration by means of association of ideas—Significance of the sexual sphere in hysterical symptoms—Criticism of the psycho-analytic method—Relation of dreams to nervous diseases—Mental rest and exercise—Reduction of activity—Relief of sleeplessness—Exhaustion as a cause of functional nervous disorder—Perimetry as a metre of treatment—Varying ways in which patients react—Advantages of sanatorium treatment.

2. Psycho-Prophylactic Treatment

Prevention of nervous disorder—Educational tasks of the psychotherapist—Question of over-strain in school—Mental defectives—Noxious influences in childhood—Education of the adult—Excessive ten-

derness and sensitiveness—Lack of occupation and luxurious living as causes of degeneration—The struggle for existence as a means of exercise—The aim of psycho-prophylactic treatment.

B. Practical Examples 315

Direct and indirect, simple and combined suggestion treatment—Relief from morbid symptoms—Severe disorders of function as a result of mere imagination —Their prompt relief through annulling the false ideas—Symptomatic suggestion treatment of various organs—Cure of hypochondriacal depression—Psychic sea-sickness—Removal of anorexia—Psychic diarrhœa and costiveness—Psychic dyspnœa—Traumatic neuroses—Other examples of disorders of function psychically caused and psychically cured.

Conclusion 338

SUGGESTION AND PSYCHOTHERAPY

INTRODUCTION

"Le plus grand déreglement de l'esprit est de croire les choses parce qu'on veut qu'elles soient."—PASTEUR.

THE most conspicuous trend of the intellectual life of our times is toward the popularization of science. The feverish activity so characteristic of modern life manifests itself, and not by any means least, in the zeal with which the results of scientific research are being presented to constantly growing audiences. The standard of general education is raised simultaneously by public lectures, by scientific essays in the daily press and magazines, and by books covering their subjects exhaustively.

It is doubtful whether enlightenment actually results from such methods, or whether they produce a certain questionable semi-education, which frequently is worse than gross ignorance. The benefit to be derived by those in the lecture audience or by the readers of the periodicals must depend on their critical acumen and independence of judgment, their ability to separate the essential from the unessential, to re-examine the facts adduced,

and, above all, to recognize what is based on conjecture and what is proved by evidence.

But from the mass of scientific material most of them absorb only what appeals to their own traits or desires. Therefore, while the object of the popularization of science is to annul *a priori* belief in authorities, and to correct blind confidence in transmitted dogmas, what really is attained is often the revival of similar belief in other forms. Such semi-education, though it produces confusion in untrained minds and excites the ridicule of those of more intelligence, generally causes most harm in the field of medical dilettanteism, that most harmful form of amateurishness. Where we are dealing with the most valuable possession of mankind, mental and bodily health, half-knowledge indisputably is much worse than crass ignorance.

Neither a knowledge of the construction and the functions of the body, nor of the more important rules of health, is to be classed as medical dilettanteism. The laws on which our weal and woe primarily depend are quite as fit objects of general education as, for instance, simple mathematics or the primary facts in history. But the popular medical literature, in its description of diseases and

their treatment, ignores those laws, produces misconceptions of all sorts, and, therefore, is detrimental and dangerous.

If the adept and experienced physician cannot avoid diagnostic errors, is it reasonable to expect the layman to recognize disease and to understand its complicated processes?

Faulty instruction on such a subject, especially when it comes from an incompetent source, certainly cannot be very beneficial. Usually such teaching leads the layman to ascribe to himself or to others some disease which is not present, or else he fails to comprehend the nature of an actual disorder, in which case he resorts to remedies which should not be applied. Volumes might be filled with an enumeration of the known victims of such medical dilettanteism, self-treatment, charlatanism, and "prayer cure." The number would be much larger were all such cases made the object of official record or juridical investigation.

Bitter experience has proved the evil of incompetent administration of drugs, and medical dilettanteism, therefore, has turned in recent years to suggestive therapeutics, on the erroneous assumption that this method of treatment, if not successful,

at least could do no harm. To the better-informed, however, it long has been clear that treatment by suggestion, or psychotherapy, if not directed by the experienced physician, may cause considerable detriment, even if only because the opportune moment for rational intervention by the competent physician has been missed.

True, the objection may be raised that physicians themselves, in speech and writing, have encouraged such pernicious instruction by taking popular methods to spread their own views. Much of the popular medical literature of recent years, in fact, is the work not of quacks and charlatans, but of competent medical authorities eager to enlighten and educate. In fact, the literary activity of the real physician has largely been forced by the pretender. Of two insurmountable evils, the trained medical man has chosen the lesser.

That it is an evil to discuss indiscriminately before a lay public the complexities of etiology, pathology, pathogenesis, symptomatology, differential diagnosis, prophylaxis, and therapy cannot be disputed, but as that is being done to an inordinate extent by persons thoroughly unqualified to express intelligent opinion on those subjects, and as the

physicians themselves cannot check such deleterious methods, there remains no alternative for the completely equipped practitioner of medicine except to wield the superior arms which science has placed at his disposal.

If the public receives the desired instruction from a source competent to give it, because correctly informed, the evil cannot be as great as when charlatans, by their writings and lectures, deliberately lead to confusion and error. Their misteaching is unpardonable, for how should those not even conversant with the fundamental theories of exact investigation assume the duty of transmitting medical knowledge? While they proclaim that their purpose is to spread enlightenment, they really are actuated only by unconscientious covetousness, frivolous presumption, and, to put it mildly, a fanaticism which is open to correction by neither reason nor authority. They speculate on a belief in the stupidity of the public, and for that reason alone make no geniune effort to disseminate true knowledge.

The scrupulous exponent of popular medical knowledge must convince the layman that it is impossible for him to diagnose diseases and to

treat them scientifically. With that principle in mind, the great Virchow, with Holtzendorf, put forth a "Collection of Popular Scientific Lectures," a work which has done much to change the attitude of the profession toward the wide promulgation of medical instruction. Not so long ago any work of that nature was deprecated as a breach of professional ethics. Fortunately for the advancement of culture, that attitude has changed.

This work is addressed to cultivated persons generally, with the purpose of helping them to comprehend the difficulties of medical investigation, and of instilling a conviction of the evils and dangers which result from the treatment of diseases by the unqualified. That this authoritative material will ultimately overcome the ill effect of the harmful literature of the day we have no doubt, for even in literary controversy Darwin's maxim of the survival of the fittest must apply. These words of Schrenck-Notzing explain the reason of much that is written here:

"Especially in view of the enormous significance of suggestion in the domain of mental life, and in view of the false impression which still sways large classes of people in their opinion of charlatanism

and wonder cure, as well as in other branches of knowledge, the proper conception of suggestion by the public can only be productive of good and enlightenment."

Competent instruction is nowhere more necessary or more difficult to obtain than in relation to the influence of the mind upon the body, and, at the same time, in no subject is the interest greater. As we have indicated before, one great office of such a work as this is to make the public realize the penalty it is paying for its ready attention to the teachings of the charlatans.

With the increasing specialization and division of labor in medicine, the science of suggestion and psychotherapy has acquired extraordinary import. Many an enigma of the mind has been solved since psychology has ceased to be a speculative science, since we know that the mental functions cannot be recognized introspectively, but can be understood only in connection with bodily processes—above all, in their indissoluble relationship to the central nervous system; since, in a word, psychology has become an exact science in which, as in other branches of natural science, observation and experiment are recognized as the only valid methods of investiga-

tion, and since the mystic darkness which has enshrouded "the soul" has been lifted. In all this progress the literature on suggestion and psychotherapy has assumed almost unwieldy dimensions, and its volume is being swelled constantly by popular writings. Excluding those which are valueless because they are the fabrications of charlatans and prayer healers, there remain many admirable productions by qualified experts which excel quite as much by the strict objectivity of their contents as by the popular manner in which they are written.

Under these circumstances, it might be considered supererogation to increase this literature by still another book. Nevertheless, there are two points which must not be overlooked.

First, science is progressive. That which some time ago may have been looked upon as a true record of existing knowledge may to-day have been enlarged or restricted. Without disregarding older views, on which modern progress to a great extent is founded, our object will be to acquaint the educated reader, of any pursuit or calling, with the newest products of investigation in the field of suggestion and psychotherapy. In so doing, of course,

it will often be necessary to refer extensively to the literature of former years.

The second point to bear in mind is that science cannot be better served than if many writers occupy themselves with the same subject. Each adduces points of view which had escaped his predecessors, starts from different premises, has different experiences, and arrives at entirely dissimilar conclusions. Thus scientific progress is constantly being corrected, so that errors can never be maintained long. My hope is that this book, in which I shall endeavor as much to give due weight to the opinions of qualified writers of various countries as to overthrow the unsupportable assertions of others, will be accepted as a guide and as a critical supplement to the earlier works.

The book being divided into the two main parts named in the title, "Suggestion" and "Psychotherapy," I show in the first part what suggestion is, how it is produced, and how it acts. From the historical retrospect it may be seen that the power of the suggestive influence of the will was well understood in ancient times, and was adroitly used by forceful persons for the attainment of many ends. In discussing suggestion as a psychic force, I take

up the startling effects which, during the period of superstition and belief in miracles, must have been ascribed to supernatural causes, and I show their dependence upon natural laws, and especially upon the close mutual relationship between bodily and mental processes. To do that, of course, I shall have to define the stand-point of science as opposed to the stand-point of faith.

It is the province of science to perceive and explain the facts of nature, but even to-day, as the attentive reader will appreciate, science often must be satisfied with simply discerning those facts without being able to understand or elucidate them. In the field of suggestion, especially does the observer note many a phenomenon which apparently cannot be reconciled with the recognized laws of nature, although the actuality of it cannot be refuted. In such cases faith repels any attempt at explanation, and assumes that the action of natural laws has been arrested by supernatural powers—in other words, clings to a belief in miracles—while science, though conceding there is a limit to the powers of human cognition, and admitting that we probably never shall achieve a clear insight into the ultimate causes of all things, insists that the con-

tradiction between "miracles" and the orderly laws of nature is merely an apparent one, inasmuch as not all those laws are yet known to us. That standpoint of science alone has made possible the remarkable progress in human discernment, and through it alone could light be created to dispel the darkness which has enshrouded the phenomena of suggestion. Thanks to unceasing investigation, much which a century ago was looked upon as "wonderful" has been traced to its natural causes, and perhaps in a century more the mystery will be removed completely from many things still considered "wonderful."

Having cleared up the meaning of the startling effects of suggestion, I proceed to explain the difference between hypnotic suggestion, waking suggestion, and auto-suggestion. In the course of the work are discussed interesting instances of suggestion produced by sense deceptions, by the power of persuasion, and by the simple tendency to imitation. Furthermore, I show that, even in the state of hypnosis, the will of the person suggesting cannot enforce obedience if the person acted upon is not susceptible to the suggested idea. I also distinguish between suggestion under normal and under

pathological conditions. As illustrations I shall use interesting examples taken in part from the observations of others, and in part from my own experience.

The second division of the book treats of the practical application of suggestion as a curative agent—psychotherapy.

Kant, in his celebrated treatise, "On the power of the mind to master one's disordered feelings by the mere exercise of will," voiced the principle that it is possible to control disordered processes by means of suggestion. I shall show the great importance in psychotherapy of distinguishing between disturbances of a functional nature—those which take their course without perceptible organic change—and those of an organic kind; for, while suggestive therapeutics finds a fruitful field in "psychic infection"—the infusion of foreign salutary conceptions in the mind of an individual with a central nervous system of enfeebled energy—it encounters much more difficulty in arousing concepts that will beneficially influence the course of organic disease. Cases of outspoken psychosis, on the other hand, are not at all susceptible to suggestive treatment. Fractures of bones, cancer, tuber-

culosis, etc., it is hardly necessary to say, cannot be cured, or even materially improved by suggestive treatment.

It is true the associated "abnormal feelings" may be removed by suggestion in such instances, though the organic alterations themselves remain. Therein, psychotherapy, as I shall show, proves a most valuable adjuvant to the surgical, medical, or other treatment which may have been undertaken. It will be demonstrated in detail how important in all such cases are the personality of the physician, and his ability to influence and to obtain the unlimited confidence of the patient, and how, on the other hand, Christian Scientists, prayer healers, charlatans, hypnotizers, and other laymen, lacking knowledge of indication or contra-indication, such as is needed to make psychological means of treatment effective, bring these means into discredit.

Dercum, writing of the psychotherapeutic movement in America, says:

"This is an age incontrovertibly of fads, an age when the unessential, the intangible, the weird and mystic are pursued, when high-sounding words and phrases take the place of ideas, when metaphysical vaporings replace scientific observations, and trivial

nothings the solid truth, when wretched commonplaces inspire admiration, when worn-out platitudes become strokes of genius, and when the imbecilities of hysteria become the final words of wisdom and of morals."

My aim in this book has been to present all that which will tend to neutralize such a state of mind among the public.

PART FIRST

SUGGESTION

I. PSYCHOLOGICAL GROUNDWORK

A. Psychology as a Natural Science

To understand suggestion as an influence on the mind we must have a knowledge of mental activity, and that, therefore, will receive our attention first, even if only an outline of the subject be presented.

Psychology, the science of mental processes, was studied for centuries in a speculative way, without any consideration of the material substratum of those processes. In all that time the dogma that body and soul were unconnected with each other and that the soul continued to exist independently after the disintegration of the body persisted unwaveringly. It was supposed that feeling, perceiving, and willing, the faculties which constitute mental activity, had absolutely no relation with activities of the body, as, for instance, breathing, digestion, and muscular action.

Even at present this view is wide-spread, not only among the larger masses of people, but to a great extent among philosophers, and even among natural scientists. This opinion, which creates an antithesis between body and soul, and which assumes that bodily and mental activities functionate according to different laws, is designated as dualism.

This speculative psychology, which lacks any positive basis, and which, starting from random assumptions, passes on to endless mistaken theories regarding the processes of the soul, has to-day been replaced by an empirical psychology which, above all, proceeds according to inductive methods of investigation—that is, it starts from observation alone and sets up doctrines only after close study of a large number of uniform experiences. Foremost of those doctrines stands the fundamental law that mental processes, like all other evidences of vital action, must be regarded as functions of certain bodily organs. To be specific, mental processes are functions of the central nervous system.

The one great reason for which empirical psychology to-day must be classed with the natural sciences as an exact discipline is this: It has become a physiological psychology, whose task, as

Wundt points out, is the investigation of that which we designate as inner experience, as contrasted with objects of outer experience, which belong to the domain of natural science. This inner experience is made up of our perceptions and feelings, thoughts and volition. Wundt says: "Man himself, not as he appears from the outside, but as he is directly represented to himself—that is the actual problem of psychology."

It is the task of psychology to recognize facts, and by demonstrating their causal relationships, to explain them. Investigation may be carried on not only by means of observation under conditions as furnished by nature, but also by means of experiment—that is, under conditions produced artificially. Equal causes under equal conditions must produce equal results. If, therefore, any experience arising from a natural happening is properly interpreted, then the same experience must result when the same happening is artificially imitated. Where the result of the experiment differs from the natural experience, it is clear there exists a source of error which must be excluded by means of further experiment.

Further, it is always most essential that observa-

tion and experiment should not in any way be obscured by previously formed opinions. Empirical psychology must be unprejudiced in investigation, as must all exact sciences. Only that conclusion can be decisive which is found in each single case, irrespective of any teaching of metaphysics and of any and every philosophic-theologic system. A recognition of these principles has made scientific methods of study dominate in psychology, and now the site in which the laws of mental life are being investigated has been removed from the library to the laboratory.

B. The Organs of Mental Activity

The facts detailed here are the products of empirical or physiological psychology, results obtained through the study of mental processes by means of observation and experimental counterproof.

The organs which make up the nervous system bring us into physical and mental association with the world about us; they keep us informed concerning all that takes place in our environment; they transmit to all parts of the body the influence which the outer world exerts upon it, and also give a variety of information regarding processes and

conditions within the body itself. Finally, they put into action every function and enable it to take its course in a proper manner.

Mental activities also are nerve processes. Such a nerve process is made up of the reception of a stimulus, the conduction of the excitation caused by the stimulus, and the response to this excitation or the reaction. The reaction may consist of movements which may be observed without difficulty, or it may take place without being directly observable. If a particle of dust is blown against the cornea of the eye, involuntarily the eye closes; if ammonia fumes reach the mucous membrane of the nose, a sneeze follows; if the hand accidentally comes into contact with a heated object, it draws back instinctively. The closing of the eye, the sneezing, and the withdrawal of the hand are reactions respectively to the excitations mentioned.

On the other hand, the aspect of a rare flower may lead me to examine it more carefully. Consequently, there remains a more or less distinct impression, a memory picture which, of course, cannot be observed by any other person. I am able to represent to myself the appearance of the flower, and to recognize it when I see it again.

The production of reactions in consequence of external stimulations is one of the fundamental manifestations of life, and is inherent in all organisms.

A nerve process, however, exists only if the reaction to an excitation occurs through differentiated nervous elements. Plants and animals of a lower grade lack nervous formations, yet even in them may be noticed reactions to excitations, as, for example, the closing up of leaves and flowers with the approach of darkness and their reopening on the return of light, the contractive movements of polyps, etc. The majority of excitation responses among lower organisms remain hidden, but the excitation may be followed by noticeable movements or changes in form. Such movements, though at times they appear to be purposeful, always are dependent on physical or chemical causes. They always take place with the same conformity to natural laws, even when the same conditions are artificially, *i. e.*, experimentally, produced—just as iron filings, for instance, change their position as soon as a magnet is brought near them.

The earliest beginnings of differentiated conducting tracts are found in the cœlentera, or plant animals. In the Medusæ, for instance, there al-

ready has been formed a double nerve ring, consisting of cells and fibres which emanate from them; the fibres take their course to the musculature, to the sensory organs, and to the feelers, or tentacles. Excitation at any point produces contraction of the muscles, and thereby a movement of the animal. The stimulus applied to the sensory organs of the Medusa sets up an excitation which is transmitted over the nerve fibres to the nerve cells. From the cells the excitation passes on to the muscles, and they contract. That process, in its entirety, is known as a reflex.

A reflex differs from the reaction process which we have noted among the lower organisms, in that the reflex is not dependent on any differentiated tracts to conduct the stimulation. A reflex consists of the transmission of a stimulation to a nerve cell by means of a nerve fibre, and the resulting production of a movement without any interposition of consciousness and will. As true reflexes in man, *i. e.*, movements which are entirely independent of the will, Hermann and other physiologists admit only the contraction of the pupil upon sudden illumination and the ejaculation of seminal fluid at the height of an orgasm. Other reflex

movements, such as the closing of the eyelids when the cornea is touched, the withdrawal of the hand from a hot object, the upward jerk of the leg when the patellar tendon is tapped, etc., may be more or

less suppressed by force of will. Even those movements which are consummated apparently automatically, respiration, heart action, digestion, and the like, may be altered by the same influence. Of what significance that distinction is in suggestion will be shown later.

Reception of stimulations takes place in certain organs which are called sensory apparatus, or organs of special sense. Vision is transmitted through the eye, hearing through the ear, feeling or touch through the skin, smell through the nose, and taste

through the tongue. To describe the process more definitely we may say that the nerve structures in the organs named transmit to the centre, the brain, specific sensory impressions of the stimuli which act on them. Through the eye only visual stimuli, through the ear only auditory stimuli, can transmit impressions. That is dependent on what is known as the law of specific sensory energy.

Having recognized the unusually important rôle which is assigned to the nerve structures in the reception of sensory impressions, and in psychic action as a whole, we must consider the formation of those nerve structures. In all the animals of high organism, man included, those structures consist of nerve fibres and nerve cells. These cells, as described in 1833 by Ehrenberg, are microscopically small formations, and each has one or more prolongations or processes. The form of the nerve cell is dependent on the number of those prolongations. Nerve cells with one prolongation usually are club or pear shaped. Those with two prolongations are spindle-shaped, and those with more than two have various irregular forms. Seen with a low power of the microscope the cells appear as a granular mass, cell protoplasm, having in its centre a glob-

ular or egg-shaped body, the cell nucleus. The prolongations or nerve fibres emanate from the surface of the nerve cell and form tree-like branches, for which reason they are called dendrites (*δένδρον* —tree).

The "psychic" cell.
(Ramon y Cajal.)

Whereas several processes or nerve fibres serve for the conduction of an excitation to the nerve cell, the propulsion from the nerve cell is effected by means of only one process, which is called the axone, neurite, or axis cylinder process, and which may be clearly differentiated from the other processes, it being the only one which can be directly followed into the nerve. To prevent the passage of the nerve excitation from one nerve fibre to an adjoining one, the axone is completely surrounded by a tubular sheath, the

function of which may be understood more clearly by comparing it with the insulating sheath of the wires in an electric cable.

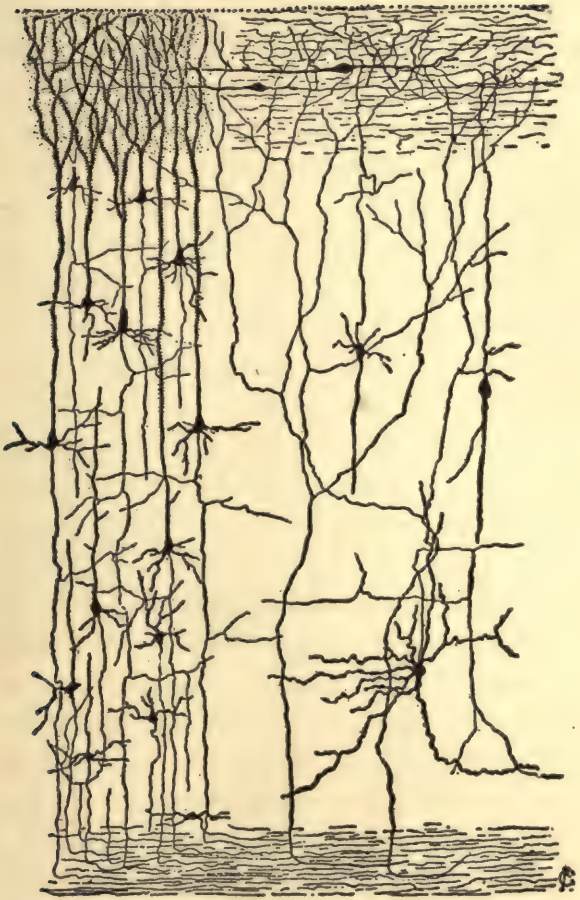
The nerve cell and all the processes or nerve fibres which pass from it are parts of a whole, a nerve unit, first conceived as such by Ramon y Cajal, and for which Waldeyer has introduced the name "neuron." The processes belong to the cell just as the extremities do to the body, and one cannot be separated from the other without suffering injury. If the nerve process be severed at any point between its end branches and the nerve cell, conduction is interrupted and excitation can no longer be transmitted to the organ or part of the body in which the nerve process terminates. A muscle becomes paralyzed, in other words, is no longer able to contract, when all of the nerve fibres which lead to it are divided. Moreover, just as the

The stages of growth of a "psychic cell." (Ramon y Cajal.)

motor nerves fail to excite actions in muscles after division of their nerve processes, so do the sensory nerves, the nerves of feeling, fail to accomplish their function when division of the nerve fibres, or pathological conditions in the nerve tissue, make conduction of an excitation to the brain impossible. Function, however, may be completely restored if a new nerve fibre grows from the stump which still is connected with the nerve cell, or if the divided nerve ends are united artificially by means of a suture.

The integrity of the nerve cell with which it was connected is essential to the new formation of a destroyed nerve fibre, for a nerve cell which has been destroyed cannot be replaced.

The brain is the central organ for all bodily and mental functions. According to Donaldson, the human brain is composed of about ten per cent of supporting tissues, blood-vessels and blood combined, and ninety per cent of neurons. The cell bodies of these neurons make up but two per cent of the entire volume of the brain, while the remaining eighty-eight per cent is made up of nerve fibres and their sheaths. These nerve fibres, axones, therefore, are mainly responsible for the size of the



The principal constituent elements of the gray substance of the fore-brain.

(After Ramon y Cajal.)

brain. In men its average weight is about 1,375 grams, and in women about 100 grams less. It is usually assumed that mental endowments vary proportionally with the weight of the brain. Still, it is an incontrovertible fact that in some persons of conspicuous mentality the brain has been of low weight, while, on the other hand, individuals with little intelligence have been found to possess very heavy brains.

Furthermore, science has not yet arrived at a definite conclusion as to whether extraordinary variations in the fissures and convolutions of the brain may be of special significance in indicating higher grades of mental processes. How old that theory is, is shown by the fact that Gall contended that brains rich in convolutions are an attribute of mentally superior persons. But that belief is not supported wholly by the facts. Gambetta, for instance, had a brain of very simple build and very poor in convolutions. It was said to weigh 1,160 grams, but later that figure was raised to 1,246, which is well below the average in weight. Another fact which upsets the theory is that brains extremely rich in convolutions have been found in persons whose mental qualities were by no means

above the ordinary. Neither the weight of the brain nor its wealth of convolutions, therefore, can serve as an absolutely dependable gauge of the mental qualities of the person.

The brain as seen from the right side, showing convolutions and fissures.

Notwithstanding the great variations in the arrangement of the fissures and convolutions of the brain, which at first view seem to be quite irregular, there is a certain positive law of disposal, so that in the majority of people the location of the fissures and the convolutions may be determined with cer-

tainty. Many investigators, including Lombroso, assume that typical peculiarities occur in the fissures and convolutions of criminals—in fact, that there are "criminal brains." Others, notably Waldeyer, deny this, and say the same deviations may be found in non-criminals.

To the cortex of the brain in man and mammals we relegate all activities which are executed with forethought and consciousness. The cortex contains a number of regions which differ functionally. Association fibres which pass from one point in the cortex to another, connecting them, increase in proportion to the increase in the number of these regions. Innumerable fibres diverge from the cortex to deeper parts of the brain. Some of those turn back and re-enter the cortex. Under the cortex lies a large layer of white brain substance consisting only of such nerve fibres and containing no nerve cells.

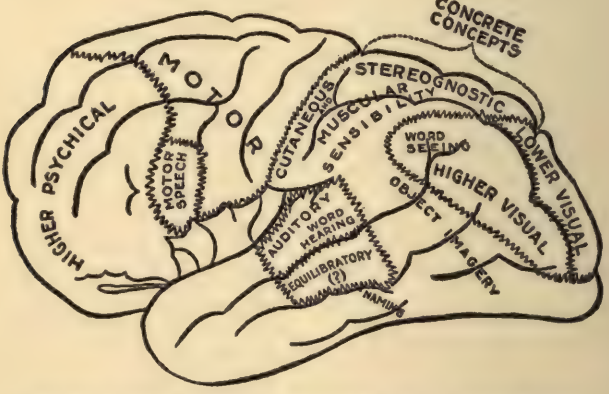
Investigations by Broca showed with certainty that all the regions of the brain cortex were by no means of equal value. Previously Gall had recognized that circumscribed destruction of the cerebrum, especially in the frontal region, produced a peculiar type of disease which manifests itself by

the inability of the sufferer to give expression to thought concepts by articulate speech, although no sign exists of paralysis of the muscles of speech or general intellectual weakness. Half a century later Broca determined that the third frontal convolution was important for articulate speech, and that in all right-handed persons—that is, in about ninety-eight per cent of the people—only the third frontal convolution in the left half of the brain was organized for speech, while in left-handed individuals the corresponding part of the right half of the brain exercises that function.

Other facts to be mentioned in the same connection are these: Hearing becomes disordered when the cortex of the temporal lobe is affected; vision is interfered with when the cortex of the occipital lobe is destroyed; smell is linked with the lower frontal lobe, and tactile sense with the convolutions of the Rolandic fissure and the parietal region.

While we have no positive data in regard to the cortical localization of the sense of taste, it may be stated that each of the so-called five senses, as well as other perceptions which make up or influence our psychic life, has its seat in more or less sharply defined areas of the brain cortex.

In addition to the experimental and clinical investigations, the developmental or embryological studies of Flechsig have contributed much to the discovery of these centres and of their localization. Flechsig's view is that the entire brain cortex consists of a number of centres.



Zones and centre of the brain according to Mills. External aspect.

While the lower portions of the brain are already formed at birth, the cerebrum of the new-born child contains only a few completed nerve conductions. These bind together the exclusively sensory parts of the interior of the body with the seat of consciousness, the cortex of the hemispheres. Following birth one sensory conducting tract after

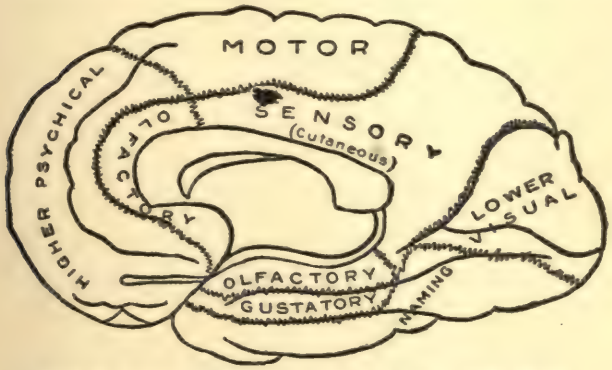
the other develops; first the one for smell pushes its way toward the cortex, and last that for hearing.

All the regions of the brain surface which physiology associates with the sensory impressions are nothing more than the areas in which lie the end-points of sense conductions in the cortex of the



Zones and centre of the brain according to Mills. Inner aspect.

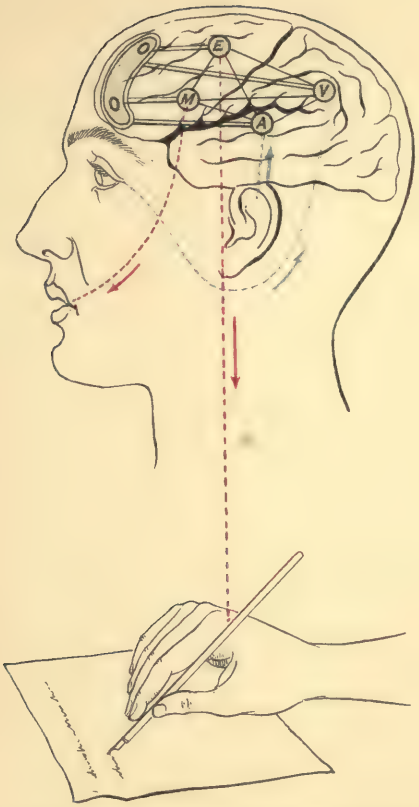
cerebrum. The largest sensory centre is that of tactile and muscular sensation. It is in the posterior central and parietal region, bordering on the region from which most of the voluntary movements are incited. It contains the termini of all conductions which are transmitted by tactile sensibility and by the organic sensations, including the sense of posture of all organs and parts of the

body—the termini, therefore, of all those conductions which bring one's own body within the sphere of one's consciousness. Flechsig calls this centre the "sphere for bodily sensations," or somæsthetic area.

Only about one-third of the cortex of the cerebrum of man is directly connected with the conducting paths which transmit sensory impressions and incite muscular movements; two-thirds are regarded by Flechsig as organs of thought, "psychic" centres. A month after birth the latter organs still are completely undeveloped, whereas the sensory centres already are entirely formed.

These "psychic" centres constitute an apparatus which combines the activity of our sense centres into a higher entity. They are centres for association of visual, auditory, olfactory, gustatory, and tactile impressions. They comprise the actual frontal lobes—that part of the brain which lies behind the forehead immediately above the eyes—a large part of the temporal and occipital lobes, a large section in the posterior parietal lobes, and, finally, the island, or insula, which is covered by the overlapping brain tissue.

The association centres of man materially exceed in size those of the most highly organized



Centres or systems of speech and their principal association (after Grasset).

animals, even those of the anthropoid apes. To those centres, above all, man owes his mental superiority, and it is they which are to be considered most in mental disease.

To-day it may be accepted as a fact that the cortex of the cerebrum represents a mighty apparatus of ganglion or nerve cells—according to Donaldson's estimate there are nearly ten billions (9,200,000,000)—the processes of which are connected in the most intricate manner, both among themselves as well as with distant parts of the nervous system. Expressed with more precision, the process of transmission of sensory impressions and the molecular movements thereby set into action may be summarized as follows:

Through the action of external influences, the elements of the nervous system, those neurons of which we have already spoken, are placed in an altered state which they then conduct and transmit to other neurons. The excitations consist of chemical changes which propagate themselves along the nerve fibres. Unimpaired continuity of the nerve tracts, therefore, is the prime requisite for this conduction, the rapidity of which is in nowise influenced by the intensity of the excitant.

The sensory nerves, or nerves of perception, which conduct external excitations to the brain and the spinal cord do not themselves feel or perceive. Neither do the motor nerves, or nerves of motion, which conduct the excitations from the brain and the spinal cord to muscles, glands, and blood-vessels, themselves induce the movement. The nerves are simply conductive organs, comparable to telegraph wires which connect the sending and receiving stations with each other, while the apparatus in which the sensation takes place and from which the motor influences proceed lies in the brain and the spinal cord. Just as severance of a motor nerve is followed by paralysis of the muscle, gland, or blood-vessel which gets its stimulus from that nerve, so will severance of a sensory nerve produce loss of sensibility in the part of the body served by that nerve. Similar results also occur, as has already been pointed out, when the nerve conduction is interrupted by processes of disease.

The entire central nervous system is made up of gray and white substance. The gray substance consists of nerve cells, the white of nerve fibres. In the large brain (cerebrum) and the small brain (cerebellum) the gray substance lies on the surface

and forms the cortex, but in the spinal cord conditions are reversed, the gray substance there occupying the interior and the white substance forming the surface. After severance of the spinal cord or interruption of conduction in consequence of destructive processes of disease, all parts of the body which receive their nerves from the portion of the spinal cord lying below the point of interrupted conduction are completely paralyzed; not only have they lost their sensibility, but they cannot be moved voluntarily.

C. Contents and Course of Mental Activity

The sensory perceptions are the ultimate elements of psychic action, not susceptible of further analysis. From them is constructed our entire ideational life, with the accompanying emotional tones and impulses of the will.

Animals, too, have sensory perceptions by which certain reactions and movements are produced in them. But the manner in which man combines and assimilates sensory perceptions is what materially differentiates human psychic action from apparently similar functions of the animal brain and places it far above them.

A classic example of that difference is provided by the history of Clever Hans, the horse which, it was asserted, had been taught by its owner and trainer, von Osten-Sacken, to count and calculate so it could retain in mind and, when questioned, indicate its own age, the age of its master, and many other numbers. The explanation of the horse's apparent mental feats, which a few years ago created considerable psychologic interest in Berlin, is due to the psychologist Stumpf and his pupil Pfungst. Both these gentlemen showed that Clever Hans, whenever making a calculation, kept close watch of the expressional movements of the interrogator, especially toward the end. If, for instance, the horse were asked to give the product of five times seven, it scraped a hoof on the ground repeatedly until a slight movement of the head or even a minimal twitch of the eye of the man gave the animal the signal to cease pawing. As soon as the horse's eyes were covered with blinders or it was prevented in some other way from watching the questioner, its remarkable mathematical ability was absent. Moreover, the expressional movements of von Osten-Sacken, or of any other examiner, were not premeditated or

intentional, as tricks designed to deceive the public, but they occurred entirely involuntarily when the animal reached the figure which represented the answer to the question.

The five senses furnish to our minds the material for the interpretation of the outer world; from the specific qualities of the five separate sensory perceptions we construct the picture of the things which surround us. In order to measure the intensity of a perception it once seemed simple to resort to the expedient of measuring the intensity of the stimulus, on the supposition that a direct relationship must exist between stimulation and perception. It soon became evident, however, that two sense perceptions of equal intensity were not necessarily produced by external stimuli of identical strength.

Under certain circumstances, for instance, ordinary daylight will act so strongly on a very sensitive eye as to cause it to close, whereas only direct exposure to the sun's rays will bring the same result in a less impressionable eye. Intensity of stimulation and intensity of perception, therefore, are not directly comparable. In the same connection we must also consider excitability or sensi-

bility, which varies in different persons, and even in the same person at different times. From that we derive this law:

The greater the sensibility, the weaker will be the stimulus, and the lower the sensibility, the stronger must be the stimulus necessary to produce the same perception.

We are led to another law by these considerations:

We all know that in the stillness of the night our attention is attracted by noises which in the bustle of day remain unnoticed. A clock ticks with the same intensity at all times, but the ticks are perceived by us in varying degree at various times. From that we learn the same stimulation will be perceived to a greater or a slighter degree, or not at all, according to circumstances. The general law which may be formulated as to such variations of perceptions is this:

The weaker the already existent stimulus, the smaller may be an added stimulation in order to be perceived; the stronger the stimulus which is already present, the greater must be the added stimulation to be perceived.

Finally, because of its important bearing on the adjustment of our sensory apparatus, we must give

consideration to this fact: Only within certain confines can we have definite sensory impressions.

There is a so-called excitation threshold below which we are unable to perceive anything, and above which no intensification of external excitation can cause any increase of perception. That excitation border is not equally high in all persons, since people differ, some being of a delicate and others of a coarse organization; nor is the excitation border always the same in any one person, as we are able to adjust ourselves in diverse ways to the reception of stimuli. There is probably no gradation which can render one more deficiently impressionable to external stimuli than that of augmenting concentration of attention.

It is recounted of a great poet that he wrote dramas while surrounded by his boisterous children. The threshold of excitation for auditory stimulation in him was so high that the noise of his immediate surroundings did not become a conscious impression.

Who has not had the experience of being so deeply immersed in an interesting book as to become insensitive to many external sensory stimuli, which, because of his undivided and increasing at-

tention, did not succeed in passing the threshold of consciousness? On the other hand, we know that the most intense light blinds us, the most intense sound deafens us, and, therefore, that a sensory stimulus above the upper boundary of excitation can cause no increased impression.

Within the limits of this book we cannot enter upon the elucidation of all the details of those processes by which impressions of sight, hearing, taste, smell, and touch are conveyed to the brain. It would lead us entirely too far afield were we to take up the theories of waves of light and sound, or to attempt a description of the receiving and conducting apparatus of the two most important sensory organs, those of sight and hearing, or of the method in which the various qualities of light, sound, the body sensations, etc., are produced.

Still we cannot refrain from calling attention to a very interesting and most appropriate diversity in the arrangement of our auditory and visual apparatus. This lies in the fact that tone perception ceases simultaneously with the cessation of the tone-producing cause, while a visual perception outlasts its causal excitation. The ear is equipped with a mechanism similar to the tone-damper in a

piano, but for which the continued vibration of the drum of the ear would cause an uninterrupted and ultimately unendurable noise. On the other hand, light impressions upon the eye persist after the stimulus is removed, a fact which is proved by the well-known experiment of whirling a glowing coal rapidly in a circle with the result that, instead of a broken line, a complete fiery ring is seen. Furthermore, the fact of after action of visual excitation explains the occurrence of so-called persisting images or after-sensations. If we gaze directly at the sun for a moment when it is setting and then at the ground or the gray wall of a building, we see distinctly at the latter point of fixation an image of the disk of the sun. Similar "after images" arise under other conditions and may be studied experimentally.

The phenomena of so-called secondary sensory impressions is equally worthy of attention. Often a sensory impression produced by external stimulation causes a simultaneous impression within the domain of some other sense for which a corresponding external impression is lacking. For instance, I may hear a loud report and at the same time see a flash of light, although there may be no

flash, or, vice versa, I may see a bright flame flash up and with it hear a report, although there be no report.

In such cases there is an unusual transfer of an excitation from one sensory field to another, an apparent contradiction of the above-mentioned law of specific sensory energy. Under normal conditions such a transfer would hardly occur, because one sense organ cannot perform the function of another. Excitation of the optic nerve always will excite an impression of light, but never a perception of sound or touch; excitation of the auditory nerve always produces only perception of sound, and never of smell or taste. A secondary sensory impression, therefore, is produced not by an external excitation, but by a perception which undoubtedly is of morbid nature. That leads us into the realm of sense deceptions, which will be considered later.

Here it will suffice to say that the lingering of sense impressions has nothing in common with sense deceptions, and that neither the memory pictures which remain as a result of sensory perceptions nor the imaginary pictures which may be voluntarily aroused by their aid can in any way

be classed among such sense falsifications. All those phenomena are indications of healthy sensory, *i. e.*, mental, action, just as, for instance, a stick which is immersed in water appears to every normal eye to be broken, and a black square seems smaller than a white one of exactly the same size.

The brain cortex, as we have already seen, is that part of the central nervous system which is most distinctly influenced by the experiences of the individual. It serves for the adaptation of the individual to the conditions of life in which he is placed. What constitutes the processes which take place in the brain is not yet clear. With Du Bois-Reymond, we must acknowledge especially that we know nothing of the manner in which nerve tracts are stimulated by ideational processes, nor how conscious perceptions are produced in our brain by external sensory stimuli.

Nevertheless, the results of modern scientific investigation force us to assume that the brain cortex possesses in a well-developed degree the ability to retain impressions which it has received, and, by means of numerous association tracts, to combine them with other impressions. We shall have to assign to the brain cortex also the capability of

transforming the excitations which it has received into movements, or of preventing the occurrence of such movements. A short survey of investigations teaches us these facts:

As a result of the varied stimulations which the external world produces upon our sensory organs, certain regions of the brain cortex become excited and give rise to perceptions of sight, hearing, taste, smell, or touch, the last class being further subdivided into perceptions such as of temperature, pressure, etc. The perceptions which arise in accordance with the excitation of the cortex pass away with the disappearance of the excitation. The cortex, however, retains a record of the excitation which persists as a memory picture, or image. That record for the time being we fail to notice, but later, when the same perception or a similar one arises, we remember the previous perception—that is, we remember that we have seen the same object, or heard the same tone, or perceived the same odor before. All our concepts are memory pictures of perceptions. Congenital concepts do not exist. The memory picture probably is not bound to those cells in which perception arises; it is better to assume that the excitation

passes over from the cells of perception to the cells of memory.

If a certain part of the cortex of the occipital lobe in man becomes diseased, the patient no longer recognizes the most ordinary things about

him unless he takes them in his hand and touches them. He is "soul-blind," and yet his eyes functionate in a perfectly normal way, for he follows objects with his vision and goes out of the way of obstacles in his path. That fact makes it extremely probable that sensory impressions and memory pictures are deposed in different nerve cells of the brain cortex. Otherwise it would be inexplicable how, notwithstanding the orderly operation of sensory impression, amnesia can persist.

Through a new combination of old memory images, pictures of the imagination arise. These play an important rôle not only in artistic activity and in scientific work, but also in every-day life, since every action or occurrence is associated with a consideration of the possible results.

The precision of an idea is dependent on the intensity, the duration, and the frequence of the occurrence of the sensory perception which forms the basis of that idea, and on the time which has elapsed since its last occurrence. If the same or similar sensory impressions do not again and again rivet the material alterations which have taken place in the memory cells, then, in consequence of metabolic influences, these same changes will dis-

appear. The molecular changes in the nerve cells which are not in any way perceptible by means of any of our present aids, become blotted out and the memory pictures are forgotten. The same process, amnesia, may also occur, as we have already mentioned, in consequence of disease in certain parts of the brain cortex. To understand how it is possible that the sensory apparatus may functionate normally while at the same time no memory picture may remain for any former sensory impression of the same or a similar kind, we must constantly keep clearly in mind the difference between cells of sensation and cells of memory.

The sequence in which concepts occur or the path which excitation takes in the brain cortex is determined by the associative connection which exists among the memory cells. The connecting tract between memory cells becomes passable as a path of least resistance in varying degree, depending on the frequence, the persistence, and the unison of excitation of the cells connected by the tract.

Under certain conditions "passable" connecting tracts—that is, tracts which are frequently ex-

cited—functionate entirely automatically. A pianist, for instance, will be able to execute faultlessly a piece which he has played frequently, and yet at the same time his mind may be absorbed in some subject entirely unrelated to the music. In the same way are explained the dangerous feats not infrequently accomplished by sleep-walkers, such as climbing over roofs, walking upon window sills, etc., feats which the performer when awake could hardly have achieved. In such persons there is, on the one hand, an exclusion of the consideration of the danger which is associated with such actions, while, on the other hand, the associative connecting tracts in the somnambulists are sufficiently passable to enable them unconsciously to carry out the movements necessary to prevent their falling or coming into contact with obstacles.

Other important elements in the current of association of ideas are the distinctness of the memory picture on which recognition depends, the emotional tone which accompanies the concepts and of which we will speak later, and the extremely variable influence of mutual retardation or acceleration which the memory cells exert upon one another. The phenomena already considered must remove

any doubt that the processes of the mind are functions of the cerebral cortex. The sensory impressions which bring our minds into relationship with the external world and form the basis of all our concepts leave in the cortex actual "imprints," molecular alterations of the nerve cells, which in turn incite other changes or movements, in the nervous system.

Psycho-physical parallelism is the term used to designate these close relations between the psychic processes and the material changes in the nervous apparatus, especially in the brain cortex—the relationship, in other words, between the action of the mind and the bodily processes. This psycho-physical parallelism has been very carefully investigated by Bumke, and his conclusions have been published in a very interesting dissertation. He arrives at this conclusion:

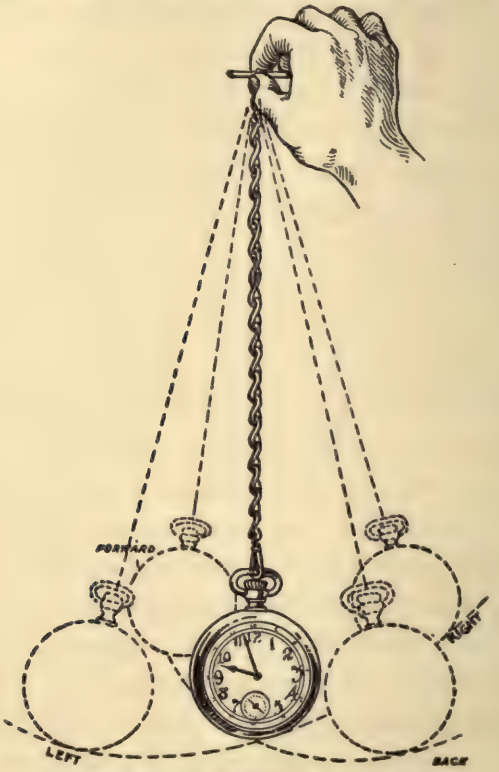
"While it is true that an impression cannot be measured, nor can it be said that it is so and so much greater than another impression, nevertheless many phenomena of mental life are open to exact investigation because every mental process is, after all, produced and excited by physical excitations which come from the outside, and be-

cause those processes almost as regularly finally lead to bodily expressions, to motor discharges which we designate as expressional movements. We are able to measure the two end links of this chain; we can estimate the stimulus by means of which the processes of consciousness are uniformly aroused, and we can analyze with precision the bodily reactions which are observed to accompany or to follow with regularity the course of these physical processes."

Bumke calls special attention to the fact that each of the various emotional states is accompanied by a variation in the size of the pupils, by a distinctly measurable variation in the rhythm of the heart and of respiration, and by corresponding changes in the blood pressure. Such expressional movements, taking place involuntarily, furnish an explanation for "mind-reading." The mind-reader, on the one hand, depends on the fact that the mere expectation of having our thoughts read leads to a corresponding action of our muscles without that action being influenced in any way by the will, and, on the other hand, he must possess extraordinary skill in recognizing minimal changes of expressional movements, especially those regulated

by the facial muscles. A slight movement of the head, a glimmer in the eyes, a deep breath, reveals to the mind-reader, even though there be no contact between him and the object of his experiment, that the hidden thought is upon the verge of disclosure. Similar expressional movements which will be interpreted as evidence of dissent instead of assent, plainly indicate that he is following a wrong track and that the solution of the problem must be sought in another direction. The trick of Clever Hans, to which we have already alluded, depends entirely on such skill. The occurrence of such expressional movements may easily be demonstrated in a rough way by the following experiment: Hold the free end of a string having a weight attached to the other, or the free end of a watch and chain, between thumb and forefinger, so that the weight will swing freely and constitute a pendulum. Bring the weight into a state of rest. Concentrate your thoughts upon the motionless pendulum and keep thinking, and saying to yourself, "Now the weight will move forward and backward"; with proper concentration of mind, the weight will, as a result of minimal, unconscious, and involuntary muscular movements, move to and fro. Then change your

thoughts to "the weight will now move from side to side," and in a moment the direction of the



Experiment showing influence of concentration of thought upon muscular movements.

movement of the weight will have changed to accord with the new train of thought.

For every sensation, for every idea, there is a corresponding brain vibration, a movement of the molecular atoms in the brain. Furthermore, every brain vibration causes a perception, an idea, whether we be in a waking state or in a dream. There can be no thought without corresponding vibration of the brain. All our perceptions, without exception, take root in the brain. I may burn my foot, prick my finger, inhale a fragrant odor, or eat a palatable dish, and in the specific instance the impression apparently is perceived in the foot, the finger, the nose, or the mouth, but it really has been transmitted by the nerves to the brain, and it is that organ which causes the perception.

Even more remarkable is the fact that an extremity need not be present at all, and yet we may believe that we have feeling in the missing member. Often a person whose arm or leg has been amputated has sensation in the missing limb long after it has been removed. That shows that the habit of feeling something in one part of the body or another may be the direct cause for sense perception. Simple imagination, an entirely internal idea, may dominate perception to such an extent that sensations of pain, intense disorders of function,

even death, may result. Such extreme cases, to which we will again refer, are numerous in literature.

That every thought, every association of ideas, is a brain vibration by which molecular movements are set up in the nerve cells is true even when the perception has not been caused directly by a sensory impression or when the perception directly follows a simple memory picture, or when it is based on a sense deception. Hence, although emotional processes, under the influence of materialistic views, were regarded as secondary to bodily phenomena, Berger has demonstrated in a convincing manner that the physical changes in the brain all are of secondary nature and subsidiary to psychic processes.

The question as to the nature of the material brain processes which accompany mental action is far from being solved, as Bumke rightly emphasizes. We cannot expect the methods of investigation of brain physiology, no matter how exact they be, to be able as yet to explain in every detail the causal connections of brain processes and mental action and their psycho-physical mutational relations.

We may as well admit that thus far in the field of physiological psychology we hardly have ad-

vanced beyond recognition of simple facts of experience. Thus, for instance, we do not even know with certainty how color concepts arise in the brain. We only know that color is present neither in the object nor in the rays of light; that it is an excitation of the retina, or, rather, of the endings of the optic nerve in the retina, although there is not the slightest consciousness of any contact between the retina and the vibrating waves of ether. While unable to give a detailed account of the manner of production of concepts, but firmly confident that exact methods of investigation must bring about a solution of the problem, we will content ourselves for the present with recognition of the fact that sensory impressions furnish the material from which the mind constructs for itself a concept or idea of the external world.

Concepts are compound formations from elementary sense impressions. One perception does not follow directly upon another, but perceptions are connected with one another according to certain laws and rules. The laws governing associative combination of concepts must be considered next.

Every concept calls up as its successor either a concept which is similar in contents or sound of

words, or a concept with which it has simultaneously arisen. Similarity and simultaneity of impressions, therefore, are the basis of so-called concept association, association of ideas.

In the first case the concept of a yellow object may be followed by that of gold, or the concept of a part by that of the whole, and vice versa. Analogously, a concept will produce its opposite, or the similarity of a word alone may lead to the serial placing of ideas otherwise unrelated. The association of ideas according to the principle of similarity was recognized even in the time of Aristotle, who adduced this example: Milk—white—air—moist—autumn, etc.

Quite as common and just as important in our conscious mental life are associations of the second kind, those based on the simultaneity of sensory impressions. Thus a single line of a poem recalls the remaining ones, a part of a well-known melody brings back the entire tune, the concept of an acquaintance calls up the idea of his dwelling, a view of a country previously seen restores the concept of the life and activity of its population, etc.

Not infrequently concepts seem to spring up in our consciousness entirely without cause, being

produced neither by external impressions nor by other related concepts—independent ideas, so to speak. If, however, we make a thorough search, the apparently broken chain of concepts may again be united so that, by tracing the course of ideas backward, we are able to discover the natural relationship between the seemingly fortuitous "sudden idea" and those which preceded it. Freud's method of "psycho-analysis," of which we will speak in more detail in another chapter, is based upon this fact.

Olfactory impressions have a remarkable faculty of reproducing concepts and pictures which in the past were simultaneously present with them. With truly magical effect the fragrance of a perfume may bring into the light of consciousness from the recesses of the memory the concept of a person, of all his attributes, and of our mutual relationships. Finally, to explain certain independent concepts which arise in us without any discoverable cause, we must remember that under the threshold of consciousness in the subconscious realm there is a constant play of processes, and that this occasionally assumes such proportions that these processes become perceivable by our consciousness.

Sense perceptions and concepts are always accompanied by positive emotional tones of pleasure or of displeasure. These emotional tones also leave their imprint in the form of memory pictures. We are angry or we are pleased, we are ashamed or we are contented, in the recollection of certain happenings. Certain emotions which are useful because of their origin and persistence as part of the struggle for existence, and which serve partly for the protection of the individual, partly for the benefit of the direct descendants, partly for the advantage of society, are known as feelings of instinct, and are congenital. Representing the inherited experience of centuries, they guide us in avoiding the injuries and the dangers which threaten the existence of man. Moral sense, or conscience, also is based, according to Exner, upon perceptions that must be classed with those social instincts which were developed in the strife for existence.

Instincts, therefore, consist in the automatic performance by man of what is appropriate in a way which is entirely independent of any process of consciousness.

The entire emotional life of man and all of his

actions are dominated by tones of feeling, by the transmission of feelings of pleasure and of displeasure from one concept to another. Therein mainly lies the cause of our sympathies and antipathies, of our prejudices for or against persons or things. Every concept is modified by numerous emotional tones, which vary both in quantity and quality, derived from the impressions which have caused the primary concept, as well as from the transmission of numerous associative connecting concepts. Thus arise all the complicated feelings and moods which, with their many shadings, are nearly always found in developed conceptional life.

The rapidity with which ideas flow, varying as it does with the individual, and not always remaining the same even in any one person, is influenced to a high degree by the emotional tone. If one is in a joyous mood, ideas flow freely and easily, one arising from the other; a depressed mood, on the other hand, dams the stream of ideas. In its most extreme form the latter condition is shown in the morbid increase of the basal emotions. In the depressed person, the sufferer from melancholia, the course of ideas is greatly retarded; the

thoughts drag lazily and the depressive picture is retained with tenacity in consciousness. On the other hand, in mania, in which a causeless, joyous excitement predominates, the associations, being frequently produced by mere external similarity of words, are accelerated to such an extent, and the coupling together of thoughts is so rapid, that a mental state ensues which may best be described by the words "flight of ideas."

Naturally, practice is another great influence in the flow of our associations. Associations which have taken their course countless times in a similar form will flow with lightning-like rapidity, while new, unfamiliar chains of thought must be arduously formed. The adept chess-player sees at a glance many possible combinations of the figures on the board, while the beginner regards each piece and slowly evolves each possible move.

It is a sign of disordered thinking when thoughts come so abruptly that the transition from one idea to another can no longer be recognized. Through the orderly current of concept flow we must be able to trace a logical connection of thought, which is like a thread of brighter color in a mass, and which, while it may skip immaterial connecting links of

associated ideas, must never lose sight of the material connection of concepts.

In the waking, fully conscious state it is the will which weaves that thread. The association laws, after all, give us only the form, not the contents of thought. They teach us how we associate, but not what we associate. In every concept the connecting possibilities are innumerable, but only certain thought connections are chosen, and the more frequently they are selected, the more infallibly do they recur. Here habit and practice play a large rôle, as already indicated. Our interest directs us in connecting the significant ideas and in disregarding others, and when this process is repeated again and again, certain currents of thought are gradually made to flow with the precision and regularity of clockwork.

Whether we choose one idea or another from the endless variety of association-material which is furnished and proffered by the sense perceptions and memory pictures is not determined by association laws, but by the personal will. It is the will which brings order into chaos, combining the percepts into correct concepts by means of which we are able to pass from positive things to those which

are uncertain and need to be proved. It is the will which occupies a directing position in the midst of the entire mental action, which weaves a fabric from the momentary sense impressions and from the memory pictures stored up in the brain cortex, and which controls the emotions that accompany our perceptions and prevents them from obtaining undue influence over our actions.

Again, it is the will which produces attention, the power of thought concentration, by means of which we are enabled for long periods of time to direct the sensory apparatus and the conceptional contents in a certain direction, without allowing ourselves to become confused or to deviate from things material to those which are immaterial. The acme of mental action is represented by apperception, that clear conception of ideas carried to our consciousness by sensory impressions combined with dependent judgments and conclusions.

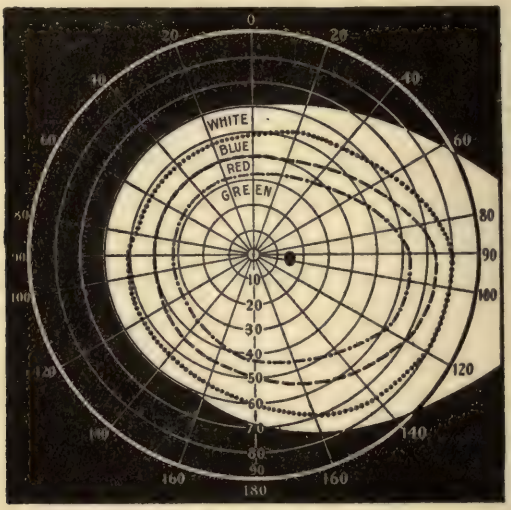
Here again we must emphasize the fact that we know nothing of the manner or method by which sensory impressions become transformed into conscious perceptions. The mechanism of thought differs from that of the most complex and perfect machine in this feature: No matter how well the

latter may operate and fulfil the most complicated functions, it never possesses any consciousness of its own activities.

For the time being we must content ourselves with accepting this self-consciousness of mental action as a fact proved by experience. To how great an extent mental processes are dependent on the conditions of bodily organs is strikingly shown by a fatigued brain. It is in direct proportion to the increase in the degree of fatigue that the brain loses the capability of recognizing clearly the perceptions produced by sensory impressions. Attention, without which apperception is impossible, wanes with an increase in the degree of brain fatigue. This fatigue may be measured in a simple manner by aid of perimetry or the test of the visual field. By means of perimetry, for instance, we can easily demonstrate in children that at the end of the lesson which has fatigued them, when they are unable longer to put forth the same amount of attention as at the beginning, their field of vision has become restricted in a marked degree. The intimate relationship between mental action and the nervous apparatus, therefore, has once more been demonstrated clearly by the dependence of

attention and apperceptional capability upon the intensity of sensory impressions.

The following incident exemplifies well the working of attention: Two telegraphers are occupied



Perimeter chart.
Normal field for white and colors. (Red, blue, and green.)

at their respective apparatus, the one receiving, the other sending a despatch. Both are experts in their work. The operator at the sending apparatus, in the sounds coming from the receiving apparatus of the other man, recognizes a familiar name and, curious to know more, calls to the receiving oper-

ator, who has transcribed the message, "What has Jenny N. been doing now?" To his astonishment, his absent-minded colleague replied, "I don't know, I wasn't paying attention," and keeps right on receiving and transcribing. This operator had been receiving messages faultlessly, had been transcribing them correctly word for word, had heard and answered the question of his friend without interrupting his work, and, as he afterward admitted, had been thinking of nothing else than his wife, who was sick at home. This occurrence shows us an automatic activity of the brain so perfected through long practice that attention could be entirely excluded from the work in hand without in any way disturbing the orderly process of brain function involved in it.

From what already has been said the dual activity of mental life becomes evident. The one element, which may be designated the objective activity, introduces to us the exterior world, while the other, subjective mental activity, recognizes itself. Just as the concepts of the objects which lie outside of us furnish the building material for thought, so the feeling of "I" or of "self," which is made up of emotional tones combined with

the sensory impressions that are transmitted to consciousness, forms the basis of the ego. Objects presented to us and the feeling of ego now stand opposed to each other as an outer and an inner world respectively. The feeling of selfhood is by no means born in us in its complete form. Just as we must learn to orient ourselves in regard to the objects in space, although the crude, vague feeling of extension, of body, as such, is innate, so we must learn to identify ourselves as individual personalities, although the "I-ness" also is indissolubly bound up with our nature.

Small children speak of themselves as individuals standing outside of themselves. The philosopher Fichte gave his friends a feast on the day his little son for the first time referred to himself as "I." The realization of plurality, of individual existences, which already is actually furnished with the nature of our minds, is consciously expressed by the individual personality, by the growing being, as soon as he recognizes himself as "I."

Therewith is taken the decisive step from simple conceptional consciousness to the consciousness of self. It is that which we call "I," or, psychologically, our "ego." Whatever the child feels, con-

ceives, wills, from the time of the transition, it feels, conceives, and wills in respect to its own "I." While the child-being was still a neutral person, it made no clear distinction between itself and other objects. For such a being there existed only a world of which it itself forms only a part. The moment that the "I" awakens, all things are divided into two worlds, an inner one, the "I," and an outer one, the "not I," a deep chasm separating the outer and the inner world, the foreign one and one's own. The ego, having awakened into self-consciousness, henceforth stands in the centre of human mental action.

The ego, the individual mind, feels only itself while it confronts everything else, perceives it. The individual mind, however, tends toward a maintenance of itself against the non-ego, the outer world. The individual emotions and instincts are directed toward satisfying the ego—they are egoistic.

It is free, uninhibited action or activity in accordance with the innermost natural laws and desires that furnishes pleasurable feelings to the ego. Limitations from the outside, by foreign power, checking of natural desires and tendencies, produce unpleasurable feelings. Since the earth, however,

furnishes only a limited space in which each individual with the same desires and traits as those of others also wishes to assert his own ego and to claim for it the place which belongs to it, the natural egotism necessarily leads to conflicts, to a competition, a battle, for the goods of the earth. On this principle of struggle, which, again from selfish considerations, leads to a recognition of foreign personalities, and which from considerations of utility makes room for altruistic feelings and thus sets barriers to the unrestrained activity of one's own will, depends the essence of existence, the entire development of the many.

Brief consideration must be given, too, to articulate speech, one of the most important expressions of mental activity, and one which distinguishes the human being from the anthropoid ape and from all other highly developed mammals. This faculty is dependent on a number of extraordinarily complicated movements of lips, tongue, palate and larynx. While the other expressional movements which arise as associates of psychic processes, such as laughing and crying, mimic movements of the facial muscles, blanching or blushing of the face, nodding and shaking of the head, gnashing of the

teeth, etc., usually serve only for expressions of the emotions and ensue more or less involuntarily, articulate speech is employed entirely in accordance with our own desires for the expression of our sensations and ideas. Speech and thought develop together and interdependently. Speech is of the greatest significance for voluntary thought.

A long and complicated process of thought can no more be carried out without the use of words, whether spoken or unspoken, than a problem in mathematics can be solved without the use of figures or letters.

The function of speech is situated in the cortex of the cerebrum. In the posterior part of the third or lower frontal convolution, the human being possesses a convolution which is entirely absent in the ape. This is the speech centre of Broca, and destruction of it deprives man of his faculty of speech.

Memory pictures for sounds of words are preserved in a certain place of the temporal lobe. Processes of disease in this location are followed by a loss of memory pictures, and the result is that words, although heard, are not apperceived. This condition is designated as "soul-deafness."

In a subsequent chapter on the mind of the

child we will recur to the development of the faculty of speech. On the other hand, we cannot enter upon a discussion of the freedom of the will, notwithstanding its apparent importance. Here we merely will say that the views of the older psychology, which assumed a special will as the cause of our actions, can to-day lay no claim to validity. There exists no proof to support the assumption that the brain cortex or any other portion of the brain can produce a movement of itself without exterior influence.

That which appears to us as free will is the result, so far as we now know, of processes in the brain cortex which have resulted in consequence of stimulation from the outer world. Our actions, therefore, are the product, just as are our processes of thought, of existing necessities, and are dependent on the law of causality.

It goes without saying that this law cannot be called upon to excuse criminal acts; that, moreover, legal accountability and responsibility for such acts remain in full force, notwithstanding the determinism of the will, unless pathological brain processes whose existence can be proven unquestionably make certain the diseased character of criminal acts.

D. Peculiarities of Mental Activity

Some peculiarities of mental activity have already been touched upon. We have seen how simple it is to explain the perilous feats of the sleep-walker and how "thought-reading" is accomplished in an entirely natural way—through the reader's highly developed faculty of observing expression-movements which arise involuntarily.

In considering this subject we should also refer to such "occult" phenomena as telepathy, distant action, spiritistic manifestations, etc. Of course, before any serious attention can be paid to such matters, the actuality of the occurrences must be established beyond doubt. This has not been done up to the present time.

As yet we have no positive or trustworthy evidence that thought transference can be effected in any other manner than by actual contact. Those instances of thought transference at a distance which are reported to have been observed are not of sufficient force to counteract the suspicion that self-deception or wilful trickery is involved in them. Even if we did admit the possibility of telepathy had been proven, we still should have

to uphold the fundamental law of all scientific investigation—that every manifestation which may be perceived by our senses can be produced only through natural causes. Science could never, without sacrificing its very self, adopt the viewpoint of the mystics, who are all too prone to explain enigmatical happenings as demonstrations of the supernatural.

Even to-day the judgment of men otherwise exact in reasoning is obscured by the survivals of a period of unbridled credulity, when all too much readiness was shown in accepting incidents as miraculous. Recognized authorities like Zoellner, du Prel, Romanes, and others have not been able entirely to free themselves of awe for mysticisms.

It cannot be repeated too often that human cognition has its limitations, but these limitations are being extended constantly through endeavors to find natural explanations for actual occurrences. Science cannot enter into any controversy with mysticism. The absence of any common basis, the complete difference in principles of recognition, render any mutual understanding impossible. Science must insist that the question of a suspension of natural laws cannot arise even in relation

to apparently wonderful happenings. It may well be that our views regarding the laws of nature will require modification as science progresses, but we must keep uppermost in mind the fact that those manifestations of mental life which still appear inexplicable are nevertheless subject to the laws governing all actual occurrences.

Flammarion, the noted French astronomer, has attempted to explain telepathy and other "occult" phenomena as natural manifestations. He cannot be classed among the mystics, for he takes direct issue with them in acknowledging that exclusively natural forces must play a part in the production of thought transference at a distance. But he accepts such thought transference as a proven fact. He says expressly that in telepathy the mind does not disengage itself from the body and rush off into space, nor does he believe any mental action can be independent of the central nervous system. Flammarion came to a recognition of telepathy as a fact because of much evidence which he considered trustworthy, and he explains it to his own satisfaction as follows:

"If we sound a string of a violin or a piano, then another string at a certain distance will in-

tonate with it and adopt the tone of the first. A wave movement of the air carries the tone with it. If we set a magnetic needle into motion, a second magnetic needle placed at a certain distance will fluctuate in conformity with the first one, by simple transfer of the movement through the air, without any contact existing.

"In Paris we speak into a telephone transmitter. The electric connection causes equal vibration of a similar plate in Marseilles. It is no substance which is transmitted, but only a wave. A star billions of kilometres distant in the infinity of the heavens is not visible to us on earth. But if I place a photographic plate behind a lens, the ray of light from the star will influence the impressionable substance and leave a picture on it. Is not this fact more astonishing than the passing of a brain wave over a few kilometers to transfer itself harmoniously upon another brain? Through the 'emptiness' of space a solar upheaval produces on our earth at a distance of one hundred and forty-nine millions of kilometers a northern light or a magnetic disturbance.

"Every living being is a dynamic centre, and every thought a dynamic action. There exists no

thought without a corresponding vibration of the brain. Is it strange, therefore, that this vibration should be transmitted in the same manner as in a telephone, or in a photophone, which transmits words by means of light, or as in wireless telegraphy?"

Needless to say, we limit ourselves to a mere reproduction of Flammarion's attempt at an explanation, without endorsing or adopting it; for even the comparison of telepathy and wireless telegraphy, in which a receiving apparatus properly attuned for the reception of electric ether waves of only the same intensity is capable of receiving despatches, shows the conditions are so disparate that they cannot be regarded in any way as satisfactory evidence that telepathy is possible. Moreover, no degree of "wonderfulness" can be a measure of credibility for science, which insists on *positive* indications.

William James, referring to experiments conducted "by a few more careful observers since 1880," says those experiments, taken in the aggregate, make it unreasonable to doubt any longer that occasionally a telepathic relation may exist between one mind and another. He adds that,

strange as it may appear, there seems evidence, small in amount but good in quality, that a person, by exerting his will, may cause himself to appear present to another at a distance. Notwithstanding James, we repeat that any serious discussion of telepathy or of other mysterious manifestations of mental activity is impossible until the facts have been established beyond doubt. The literature on this subject still appears to be too chimerical for acceptance as the basis of any explanation which would satisfy the logic of cause and effect or which in the light of subsequent research would not prove absurd.

Among the peculiarities of mental activity must also be classed that enhancement of the psychic, more particularly of the intellectual, faculties into superiority over the average endowment, which constitutes the essence of genius.

Genius differs from talent in its capability of finding what is new. Talent is great only in so far as it imitates and modifies existing models; it lacks productive force. Genius, on the other hand, travels its own roads; it manifests itself not in reproduction but in the generation and the development of new thoughts. While in exceptional cases

genius may cover equably all the intellectual faculties, in the vast majority of instances it is one-sided. There are geniuses in mathematics, in language, in music, or in other fields, but rarely is there one in whom are combined manifold productive abilities.

The traits of genius usually develop at the expense of other capabilities, so that the productive capacity in one direction towers far above the average, while the capability in other respects remains far behind the ordinary. The plus on the one hand is offset by a minus on the other. This disproportion frequently is so marked that it borders on the pathological and leads us to suspect a relationship between genius and insanity. At any rate, geniuses of entirely normal mind—that is, those having extraordinary capability in one field without any corresponding defect in another—are exceptional.

That this should be so is quite comprehensible if we but consider that brain energy cannot expend itself entirely on one function without causing a stunting of the activities of the remaining ones. Genius always is innate—frequently a heritage from far-distant ancestors. It is not always transmitted to direct descendants. For generations it may remain latent, and then manifest itself un-

expectedly, often doing so under completely unpropitious external conditions. While the conditions of heredity in this regard are still understood in only a limited degree, we do know from experience that genius enforces itself with the strength of nature's elements. There is no exaggeration in the statement that if Raphael had been born without hands he would nevertheless have become a great painter. In Beethoven's case we know that some of his most marvellous tone elaborations were produced when he was almost totally deaf. Many more examples might be given to show that genius will attain its predestined height in spite of adverse external conditions.

In the genius the sensory impressions and the memory pictures are crowded with coercive force into a definite course, the powers of attention and apperception concentrated to such an extent on a certain object that the existence of the remaining world is practically ignored. This accounts for the extraordinary abstractedness, or absent-mindedness, which has so often made great scientists and artists objects of ridicule.

The new idea which absorbs the individual's entire interest has its life history like the human

being who has conceived it. Like him it is a new creation, like him it has originated from an insignificant germ, has taken form, has developed, and has been brought forth. No human brain, not even that of the greatest inventive genius, can continuously bring forth new ideas. Genius cannot be acquired; it must be innate. Where the disposition for genius is lacking, it cannot be created through indefatigable endeavor. Still, no genius can assert itself without persistent work. Genius does not produce without effort. "Inspirations" do not appear as finished manifestations. In order not to go astray during acts of thought association, genius requires assiduity, persistence, and material concentration of the will. The psychic process of the genius differs not in kind, but only in degree from that of other persons.

Like the manifestations of ordinary mental action, the manifestations of genius are dependent on the acquisition of a train of ideas in consequence of sensory stimulations. Genius unattended by extensive knowledge may be compared to a skilled workman who for want of proper material or tools is unable to carry out his ideas. That which gives to genius its predominance is the facility with

which, in consequence of its perspicacity and extraordinarily delicate powers of combination, it is able to recognize the orderly connection of complicated conditions and almost intuitively to grasp their significance.

Sleep also is one of the peculiarities of mental activity in which the psychic processes normally experience an alteration. When external stimuli are excluded and the cells of the cortex become fatigued, association comes to a pause and there ensues a condition of unconsciousness which we designate as sleep and which differs essentially from unconsciousness due to fainting or an extravasation of blood into the brain.

During sleep a more or less complete arrest of all psychic processes occurs. Dreams are the only exception to that rule. The most important function of sleep, that of giving the nerve elements which have become worn during the waking state a chance to recuperate through brain rest, is frequently hampered by the concomitant of sleep, the dream. Active and restless dreams interfere with the recuperative effect of sleep.

Dreams, according to Wundt, are fantasy pictures, hallucinations, which at times seem to pos-

sess all the reality of sensation and consequently are taken as real sensations by the dreaming person. Dreams are memory pictures of recent and remote happenings which, in a lawless play of association of ideas, become indiscriminately intermingled. They have a superficial resemblance to normal activity in so far as they connect the memory pictures into new and unusual relationships. But they differ from normal activity because the control of the governing ego is wanting, the connection of the memory pictures in dreams being planless.

Dreams are especially frequent at the time of falling asleep and shortly before awakening. The conscious life of the day does not, of course, cease at once, nor does it begin suddenly. In the condition of half-consciousness which intervenes, the action of external stimuli on the power of perception is not shut out entirely, and dream perceptions arise out of the incompletely perceived sensory impressions. Just as perceptions attach themselves during waking consciousness to any external or internal excitation, so do the pictures of a dream accompany excitations.

It is generally recognized that any interference

with the power of breathing produces a sensation of oppression in sleep, a nightmare. Folk-lore attributes nightmares to an incubus or evil spirit which oppresses people during sleep. The Germanic peoples speak of them as "Alp Druecken," and laid the cause to ghost-like beings, "Alpine mannikins," who seated themselves on the breasts of sleeping persons. A superstition among the Chaldees brought forth tales of demons whose nightly practice it was to wrestle with human beings.

Easy, unobstructed respiratory action, on the other hand, undoubtedly produces in dreams the idea of flying. The feeling of a long and abrupt fall is the result of sudden relaxation of the muscles of the legs. It arises, for instance, when the legs, after being flexed and drawn up, are suddenly extended.

Dreams run their course with wonderful rapidity, long periods of time seeming to be traversed in a moment. That is explained by the fact that dream pictures are almost exclusively visual pictures, which unfold themselves before our eyes like scenic paintings. In a few seconds a dozen pictures may alternate in our dream consciousness,

and this suffices to produce a long dream. Hence it is known that the same external stimulus often causes the dream, as well as the awakening. Dressler cites a very instructive example of this kind, as told by Mouchart.

"I was sick," narrates Mouchart, "and was lying in bed. My mother sat next to me. I dreamt of the Revolution. I was present at the bloody scenes of murder, was summoned before the revolutionary tribunal, and saw Robespierre, Marat, Danton, and all the others who had made a name for themselves in that dreadful time. I argued with them, and finally, after a series of occurrences which I cannot clearly recollect, I was condemned to death. In the presence of an enormous crowd of people I was placed upon the cart and led to the place of execution, mounted the scaffold, and was tied to the board by the executioner. The axe fell and I felt my head being separated from my body. With this I awoke, in the most dreadful fear, and discovered that a bar of the four-post bedstead had become loosened and had struck me in the back of the neck like a guillotine. My mother assured me that this occurred in the moment I awakened."

Evidently, therefore, the sensation of a momen-

tary stimulus was sufficient to produce this long dream which could only have lasted through the few seconds required for the process of awakening.

By dream analysis—that is, by tracing the association of ideas which attach themselves to the single, detached, incongruous elements of the dream—Freud has been able to fix upon a number of important facts. He differentiates:

(1) Dreams which are fraught with meaning and at the same time comprehensible, which, without effort can be assigned to a place in our mental life.

(2) Dreams which are connected among themselves and have a distinct meaning, but appear strange because we do not know where to classify this meaning in our mental life.

(3) Dreams which are unconnected, confused, senseless.

In the first category belong the dreams of children, which fulfil all the wishes that have arisen during the day and gone unsatisfied. Such dreams occur also in adults. Nocturnal thirst, for instance, makes a person dream of drinking. During the night preceding a journey a person not

infrequently dreams of having arrived at the destination.

The dream pictures of the second class probably are composite, made up of different things seen or experienced.

The majority of dreams belong to the third class. In a dream the memory pictures are transformed into an actuality and become mingled together or condensed, the significance of any single idea being displaced. Where such displacement is lacking, the dream is simple and comprehensible, but where everything material is replaced by something unessential, the dream is dark and confusing. If such dream displacements are rectified by means of analysis, we see that every dream is attached to vivid memory pictures or to impressions recently received.

Dreams never concern themselves with those things which do not enter our thoughts during the waking state. It does happen, however, that long-forgotten ideas, perhaps because of some stimulus, crop up in a dream out of the subconscious. This may appropriately be compared to the apparent disappearance of starlight while the sun is in the skies. The stars also shine in the

day, but their light remains unperceived because it is lost in the much stronger light of the sun. Once the sun has set, the innumerable lights of the stars appear, now no longer obscured by the dazzling brilliance from the larger source. Thus also in a dream do darker perceptions and memory pictures arise which during the waking state are submerged by deeper and stronger subjects of interest.

Until most recent times certain philosophers have assumed the basis of dream life to be a special condition of the mind, which they have designated as an exaltation to a higher plane. Schubert, for example, regards the dream as a liberation of the mind from the thraldom of external nature, a disengagement of the mind from the shackles of sensuality. Others have gone still further and have attributed to dreams a significance of prophecy, regarding them as being propitious or inimical demonstrations of higher powers.

Considering the interest which dream life has aroused in all peoples from time immemorial, such aberrations and fantastic conceptions are quite comprehensible if one but remembers that speculative conjecture, untrammelled by any laws of

actuality or by any consideration for facts of experience, has no limitations. Unprejudicial observation, however, has demonstrated, as must have become evident from the preceding discussion, that in sleep as little as in the manifestations of mental activity during the waking state can anything of a mystical or mysterious nature be discerned.

Sleep is nothing more than a diminished state of waking life. The mental processes which run their course during sleep are mostly after-tones of waking life, or special products of consciousness, the evolution of which has been aided by the suppression of external stimuli and purposeful trains of thought. The waking consciousness refers its entire perceptional contents, all its feelings, endeavors, etc., to itself, to its ego, which, so to speak, occupies the central throne and directs the whole. During sleep this conscious, voluntary supervision is absent, and dreams therefore evolve themselves in accordance with their own laws, wherein varied bodily states, like indigestion, oppression of the heart, obstacles to free respiration, exaggerated irritability of the nervous system, etc., do not remain without influence.

Peculiarly enough, dreams generally are forgot-

ten with great rapidity. Therefore it is doubtful whether a perfectly dreamless sleep is possible, one in which consciousness is entirely obliterated and only the automatic movements, heart action, respiratory movements, etc., are carried out. Another characteristic of dream life is the almost complete absence of active movements. Only in very vivid dreams are such movements made. Talking and singing during sleep are more frequent. Of sleep-walkers we have already spoken.

The peculiarities of the child mind, the male mind, and the female mind remain to be considered briefly. After experimental and clinical investigations had succeeded in assigning the functional seat of the perceptions which make up or influence our mental activity to more or less circumscribed portions of the brain, the embryological investigations of Flechsig aided much in the more accurate determination of those centres. These investigations of Flechsig explain how it is that the new-born infant, although it reacts to certain stimuli in a certain manner, executes muscular movements, responds to feelings of displeasure by screaming, etc., nevertheless lacks any power of associating ideas or of consciously joining sensory

impressions and possesses not the least feeling of self—in a word, why the child has no apperceptional capability.

We can observe in the infant how the faculties of conscious seeing and hearing develop, how from the most insignificant beginnings that activity of the mind arises which essentially differentiates the human being from the animal. The new-born child makes no movements, or scarcely any, which can be called voluntary. The only movements which occur are reflex or automatic. Under a bright light the pupil contracts; painful irritations of the skin, even during the first week of life, regularly incite reaction movements. Sucking is a purely reflex action. Only after several weeks from birth does the child perform movements of psychic origin.

From the moment of birth numerous sensations stream through the sense organs and leave their impress on the brain in the form of memory pictures. Through the association tracts, the excitations reach the motor nerves. At first the resulting movements are irregular and purposeless. Only toward the end of the fifth month does the child grasp with any certainty at objects which it

sees, and only from the sixth to the seventh month is the grasping of objects effected by means of the shortest route.

The selection of appropriate movements is acquired essentially by practice, and in quite the same manner as the adult acquires a new movement. Through frequent repetition the movements become more certain and are carried out in their correct sequence and with appropriate force; they become "co-ordinated." The extraordinary rapidity with which the child learns to carry out co-ordinated movements is explicable only by the inherited favorable disposition of its association mechanism.

Through practice co-ordination can be almost endlessly increased. According to Du Bois-Reymond, the value of gymnastics as taught in the German schools rests above all in the training of the co-ordination of movements for the maintenance of equilibrium and for alteration of posture. "The youthful body exercised according to the German manner," he says, "has the unusual advantage that, like the well-trained mathematician who has a method for every problem, it is provided with widely varied movements for all post-

ures of the body." How highly co-ordination may be trained is well shown by the virtuoso on the piano or violin and by prestidigitators.

Of especial interest is the manner in which the child learns to talk. According to Zander, talking is always preceded by comprehension of speech. Most children are able in the second half of the first year to understand simple words, for they turn their heads and stretch out their hands toward objects mentioned to them. The formation of words follows very gradually. The infant not only executes movements with arms and legs, but also makes use of the muscles of the larynx, the tongue, the palate, and the lips, and the resulting tones and noises apparently afford the child much enjoyment. In that way all vowels and consonants ultimately are produced, and later, by imitation, the child forms words. It accomplishes that, however, only after many futile attempts, just as it has to learn to regulate the movements of prehension. Having once learned to designate certain things by certain words, the child at first uses any single word to refer not only to a thing or object, but also to express a wish or a mood which grown-ups would indicate by means of a sentence. The word "chair,"

for instance, is used by the child to intimate, "My chair is broken," "My chair is not here," "I should like to be lifted into my chair," or other things.

About the beginning of the second year words become associatively joined with the percepts of objects. In the third year a normal child can differentiate almost one thousand objects according to their special characteristics, and can express such variations by the words at its command. Conscious perceptional life and the power of apperception, therefore, are already well developed at that age. But the mutilation and the distortion of words which are so characteristic of the child's speech and are due to lack of practice in the use of co-ordinated movements of the lips, the tongue, the palate, and the larynx necessary for the formation of speech, cease only toward the end of the fifth year.

The child is not free; it is a coerced being whose actions are not governed by motives, but are dependent on all possible contingencies until practice and habit force the actions into a certain direction and give the child a certain impress, its character. All education and character formation are based on a firm belief in the dirigibility of the

will by means of the development of the understanding and a refinement of the feelings which, acting as inhibitory factors, oppose and enable the maturing being to resist unbalanced and unstable impulses. Nature is not character, otherwise merit could not be rewarded nor crime punished. Character constitutes what training has made of congenital proclivities, in a good as well as in a bad sense. Upon that our responsibility depends.

Consideration of the individual peculiarities of the male mind and the female mind shows they are the result of the arrangement of nature, which assigns different functions to each sex.

Nature is inexhaustible in the construction of new forms. As a matter of fact there do not exist two living beings entirely alike. With the higher development of the organisms the differentiation becomes more and more evident. Nature requires for the fulfilment of its multitudinous functions all possible varieties, which mutually stimulate and complete one another. Especially does that most important office of nature, propagation of the species, require a differentiation of the organs into male and female.

In the human being, the different functions de-

volving on man and woman are the immediate cause of the marked variations in the build of the body. Those variations are noticeable not only in the primary sexual characteristics, the organs which serve directly for the propagation of the species, but also in the proportions of the body, the skeleton, the muscular system, etc. These bodily differences correspond to very marked peculiarities in the mental action of man and woman, which, as we shall see, are not the result of cultural development, but are the necessary outgrowth of natural laws.

Everybody knows that, in the man, the intellect predominates, and in the woman the emotions; the man thinks chiefly in abstract concepts, the woman essentially in concrete pictures; the man looks on things as they are, the woman as she would have them; the man has the stronger powers of apperception, the woman the more lively imagination and a greater susceptibility to mysticism; the man is more energetic and inconsiderate, the woman more gentle and scrupulous.

Those, of course, are only the general differences between the two sexes. A sharp line of demarcation does not exist in the mental activity of the two. Numerous transition phases, as well

as mixed forms, sometimes even men of a marked female type and women of a pronounced male type, physically or mentally or both, may be noted. It is quite clear that the characteristics of the male or the female mind can be dependent solely on a different organization of the brain.

The differences between the male and the female brain have not yet been investigated in all their details. While certain investigators have found the female brain to weigh less and to have less well-pronounced convolutions than the male brain, others have asserted that the size and the microscopical appearance of the various brain parts are precisely the same in both sexes, and that, therefore, any existing difference must be sought for in the structure of the cells. However that may be, the differences in the organization of the male and the female brain, with the dependent distinctiveness in mental action, constitute facts which cannot be overthrown, and which, moreover, conform thoroughly with the purposes of nature.

To man, in consequence of his more aggressive disposition, falls the struggle for existence; to woman, because of her more passive traits, fall

the making of the home and motherhood. In man are found united all the qualities requisite for the acquisition of the necessities of life and for the protection of the family. The woman possesses, above all, those traits which fit her for the care of children and for the manifold duties of a household.

Nature does nothing by halves. It has given to man not only stronger muscles but also the more penetrative understanding. To woman it not only has assigned the task of bearing children, but it has given an inexhaustible treasure of tenderness, without which the care of the helpless, the feeble, and the sick would be impossible.

That comparison of the mental distinctions of man and woman proves there can be no question of superiority or inferiority of sex. Man and woman are of equal value. The contrasts between them are such that the minus on the one hand is always counterbalanced by a plus on the other; an existing deficiency in woman always is compensated for by a corresponding advantage in man, and vice versa.

Far be it from any one, therefore, to say that woman should be subordinate to man. The ful-

filment of the functions for which nature has chosen and equipped her is quite as important as are those missions which fall to the lot of man. Man and woman mutually supplement each other, just as do the different yet equivaluable complementary colors, red and green. Hence, if woman strives to free herself from oppression to gain that freedom which the unhampered development of her individuality justifies, she is battling in a good cause. As soon, however, as she attempts to imitate man in thought and feeling, her effort is transformed into folly. In doing that she sacrifices her attractive individuality without ever attaining the goal of her endeavors. Existing exceptions to the rule simply corroborate it. It is this species of denature against which Moebius takes up arms in his well-known work on the physiological weak-mindedness of woman.

Moebius by no means looks upon woman as inferior to man. He shows how she surpasses man in qualities of the heart, in patience and perseverance, in the capacity for suffering and deprivation, in powers of love and of hate, while she stands below man in strength of intellect and judgment, in the faculties of keeping apart per-

son and thing, and of reacting to objective reasoning. This "weak-mindedness" Moebius regards as physiological, a normal state preordained by nature. Woman, according to Moebius, becomes a sterling being not by entering public life, not by aspiring to political equality with man, or by turning to scientific vocations, but by fulfilling the functions of motherhood, for which her bodily as well as her mental individualities have been specially cast.

No amount of effort will develop properties which are not already present in the seed. If, however, the development of the female brain is directed forcibly into paths for which woman has not been destined by nature, then those qualities which are to fit her for the state of motherhood must become dwarfed. Moreover, all the acquirements which are not in accord with her innermost nature will always retain a dilettantish character.

Furthermore, Moebius emphasizes the fact that certain deficits in the purely intellectual sphere of woman's life cannot be considered defects, since they are amply equalized by superior capabilities in other directions. It is just those capabilities which enable woman, in case she does not succeed

in attaining her natural destiny through marriage, to enter other vocations without in any way acting contrary to her proper self.

Professor Max von Gruber, the well-known hygienist of the University of Munich, has recently expressed himself similarly on that subject. He says:

"I once was among those who believe that if we only would give woman the opportunity she soon would show what she could accomplish in a mentally productive way. But the older I get the more evident does it become that I was in error. As a matter of fact, I cannot recall having received from a woman, either in scientific or purely intellectual fields, any new point of view, any idea of her own production, which has helped my progress, while hundreds of inspirations have come to me from men. And history does not teach us differently.

"Note the positions of honor which the Germanic and other peoples have opened to women; note the exuberant enthusiasm with which men have greeted every woman who seemed to be coequal in accomplishment. If we compare those instances with the productive accomplishments of

women in science and art, in State government, we must give up every hope that woman, in carrying on man's work, will ever be able to achieve the same results. Efface everything in those fields which women have produced and you will hardly notice the gaps. Only in the reproductive art of the actress, the singer, the musical virtuoso has woman accomplished anything really predominant. And also in the field of romance, where the great George Eliot will always maintain her place beside the greatest of men. . . .

"Individual women may be suffered to seek their fortunes on the same roads as man, but neither the individual nor the nation can be excused if the mass of talented women be enticed into these paths. . . . The worst is to be feared from the obtrusion of women into leading positions. Sober routine would consequently be dilated, short-sighted utilitarianism and dilettantic superficiality would flourish. . . . Man and woman are thoroughly different. The woman is not of lesser worth, but of special worth. Just as woman is physically different from man, even to her flesh and bones and to the coloring matter of her blood, so, too, is she different mentally. Just as she is

constructed physically for motherhood, so does she conform mentally to that, her main province. It cannot be emphasized enough that the assertion that the differences between man and woman are a result of civilization is perfectly nonsensical."

E. Disordered Mental Activity

An exhaustive treatise on mental disorders is not within the scope of this book. There is no occasion for taking up the subject at length because well-defined psychoses, for obvious reasons, are not amenable to psychic treatment and therefore are of little interest here.

We must never lose sight of the fact that neither in a normal nor a pathological sense is there any mental activity which is not dependent on the central nervous system. Just as healthy mental action is a product of the healthy brain, so diseased mental action is an output of the diseased brain. Certain psychiatrists as late as the middle of the last century believed mental disorder was a condition bearing no relation to the bodily organs and, therefore, that it had to be treated with psychic remedies, by controversion of the delusions, etc., but that view has long been recognized as an error.

Doubtless reckless dissipation, alcoholic and sexual excesses, etc., may cause a shattered nervous system, thereby facilitating the outbreak of psychoses. That result is the more likely if the excesses have been preceded or accompanied by syphilitic infection. Therefore, with Heinroth, we might look upon psychic disorder, in a certain sense, as the result of sin, or, with Ideler, designate it as an excrescence of passion. In such cases, however, more recent investigations have proven that not infrequently pathologically altered nervous systems already had existed and were a cause of the irregular mode of life. Besides, it is also possible that mental strain, intense fright, and other psychic irregularities may be followed by mental disorder, but that is because the disturbances bring about organic changes.

The distinct changes in the brain which lead to psychoses are not always recognizable by our present methods of investigation, especially when they consist only in minute changes in the cell structure, transitory anæmia, or hyperæmia, toxic conditions, etc., but when such changes are present they are the cause of the disturbances in the functions of the brain. The alterations in mental activity in well-developed psychoses cannot be corrected so

long as the cause, the actual changes in the brain, continues. But, since such changes cannot be eradicated by psychic treatment, as we said before, the more severe forms of mental disorder need receive little consideration here, and reference need only be made to them where it appears necessary to elucidate those psychic processes which are on the boundary line between health and disease.

In this book we limit ourselves chiefly to those irregular mental activities which, while they cannot be called normal, are amenable to psychic treatment because they are not dependent on organic changes in the brain.

The transition from health to disease is frequently so gradual that it cannot be stated definitely where health ceases and disease begins. Just as we find it impossible to draw a sharp boundary between health and disease in anatomic conditions or the functioning of special organs, so we may encounter many psychic peculiarities, perversities, and eccentricities which, although they attract attention and challenge criticism, cannot be called psychoses. We must not forget that the false ideas which may attain great power over all our mental activities are not necessarily products of a diseased brain.

Frequently they are connected with difficulties in digestion or other bodily disturbances.

In this connection we must mention, above all, those persons who are hypochondriacally inclined. As is well known, they never cease watching themselves with anxious care, and popular medical books lead them to diagnose all possible dangers to their health from the most insignificant changes in their well-being. In many other ways does reading play a great part in the production of false concepts. Numerous eccentricities may be referred back easily to the reading of fantastic tales. Persons of fanciful disposition, of seclusive tendencies and lacking inclination to mix in the actualities of life, frequently construct an entirely false conception of the world for themselves from books. Much of the bias and many of the whims of introspective persons are due solely to their lack of judgment in recognizing the misrepresentations in books.

In many people there exists a certain receptivity for distorted ideas, which becomes increased in proportion to the insufficiency of their education and intelligence in guiding them as to the critical reserve which they should maintain toward the

subject-matter of their readings. In a simple man of the people, for instance, the conviction that the sun moves around the earth might be regarded as a mere error, while in a man of education, one of sufficient insight to recognize that as a false notion, the same conviction would have to be looked on as a disordered idea.

The entire history of civilization confirms the fact that false concepts frequently arise from an absence of insight. Into the late Middle Ages, and even into modern times, the conceptions of the laws of nature, of the essence of physical, chemical, and developmental processes, moved in entirely false paths. The delusions into which alchemy and astrology degenerated to-day appear to us entirely insane. In the same class belong all the medical superstitions, which were due in part to the dogma that diseases were dispensations of mysterious powers and in part to the fact that deductive methods of investigation could not possibly lead to clear appreciation of the processes of nature. Those deductive methods of investigation, which started from general propositions without regard for the facts learned from experience and observation, and drew conclusions concerning

individual processes from *a priori* assumption, entirely intellectual in origin, without any proof of their truth, must be designated as the original source of all those false ideas which prevailed for hundreds and thousands of years in the entire field of culture. When such notions flourished, he was regarded as deluded who, having advanced beyond his contemporaries, was able to recognize the fundamental error and to sweep aside the "system" thought to represent an infallible truth, substituting for that "system" the contrary principle that single facts must first be recognized, and that from a series of such observations only could general doctrines be formulated. As late as the middle of the last century, Julius Robert von Mayer, who was the originator of the mechanical theory of heat, and to whom we are indebted for the law of conservation of energy, was sent to an asylum for examination as to his mental condition. So it might happen even to-day that insanity might be laid to any extraordinary man who could soar to such mental heights that his contemporaries could not understand him.

The atheist or the agnostic may look on certain religious views as delusional; the unlearned man

fails to grasp the concepts of the scholar, and the latter finds himself entirely astray in the circle of ideas of the illiterate. Still all those who, being under the influence of false concepts, fail to understand one another may be perfectly healthy in mind and capable of correct apperception and logical thinking.

False concepts, in themselves, are by no means evidence of insanity. Only if correction is impossible may such ideas be looked upon as symptoms of mental disorder. Such imperviousness to correction always is encountered where organic changes have occurred in the brain, and it militates against or completely excludes orderly association of ideas. That explains why insane delusions cannot be overcome by argument. When a person's powers of apperception react only to false concepts, it is misguided effort to attempt to talk him out of his delusion by argument—that is, by awakening contrary concepts.

As examples of the futility of such effort we need only refer to the causeless outbreak of hilarity or anger in the maniac, the equally causeless states of depression of the melancholic, and the nonsensical ideas of grandeur of the paretic. Not only is the

endeavor to oppose such false concepts by means of argument useless, but it is directly harmful in that it causes the patient to become unnecessarily excited. To-day argument of that nature is employed only for diagnostic purposes.

In those cases, of course, the physician does not know *a priori* whether the false concepts are due to a want of insight or whether they are evidences of a disordered brain. If they are due to a want of insight, they are open to controversion and correction; in the other case they are not. An investigation of the mentality is the only method by which the truth can be ascertained with certainty. The importance of this differentiation and knowledge for the purpose of psychotherapy must have become sufficiently evident from what has been said previously.

A frequent source of psychic disorder in otherwise healthy persons is false sensory perception. That may be due to various causes. In consequence of excessive fatigue, for example, the attention and the power of perception become restricted, so that exact observation is hindered.

How great a rôle fear and other severe emotions play in the falsification of the sensory perceptions

is shown most strikingly in the "seeing of apparitions," which occasionally afflicts people who otherwise are entirely clear-minded. Similarly the sensory perceptions may become clouded by febrile diseases, by anæmia or hyperæmia of the brain, or by narcotic poisons. Since all our ideas are the outgrowth of sensory impressions and memory pictures, deductions and opinions based on false sensory perceptions must necessarily be false. When false concepts fasten themselves in the mind and unswervingly oppose correction, then a disorder of psychic activity is inevitable, especially as the emotional tones and the will impulses which accompany such concepts add in their turn toward forcing the mental life into a false direction.

Stoddart differentiates three forms of disorder of perception: (1) Imperception, (2) hallucination, and (3) illusion.

Imperception consists in the inability to combine with a sensory impression the idea which normally corresponds to it. We have already become acquainted with "psychic blindness." That depends on imperception, and the same is true of the inability to comprehend the meaning of spoken words or to recognize the sensation of taste, smell,

hearing, or touch. Such imperception, of course, may be looked upon as a mental disorder only when similar sensory impressions, in a series of experiences, have failed to produce the proper perception, and when only those concepts and memory pictures are lost which are connected with such impressions. On the other hand, the inability to interpret correctly a sensory impression experienced for the first time cannot be called an imperception, since in that case the thought connections for comparison and differentiation of characteristics are wanting. Hence there can be no suspicion of imperception in children who have not yet learned to differentiate their sensory impressions in an exact manner.

By hallucination is understood the seeing, hearing, smelling, tasting, or feeling of something which does not exist. Hallucinations are not produced by external stimuli, but in most instances are due to memory pictures of especial intensity. This is confirmed by the fact that persons born blind never have hallucinations of sight, and those born deaf never have hallucinations of hearing, whereas in cases of acquired disease or destruction of the peripheral sense organs, sensory deceptions of that

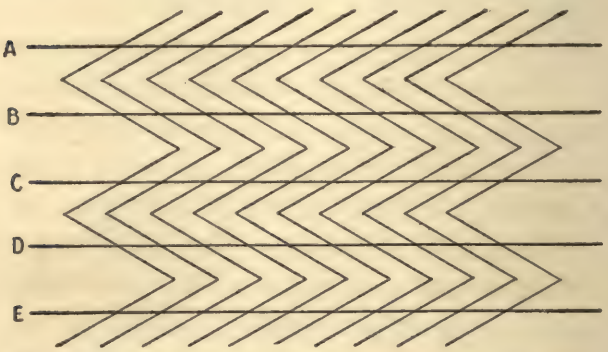
nature are common. Hallucinations have precisely the same distinctness as actual sensory perceptions, and therefore only by careful observation and logical deduction can it be ascertained that they have not been produced by external stimlui.

We must not neglect to mention that hallucinations may be voluntarily produced by artists and other people with very lively powers of imagination. A fitting example already mentioned is that of Beethoven's ability to hear his compositions when in a state of almost total deafness. In this relation, too, we may recall the well-known hallucination of sight which Goethe experienced on the road to Sesenheim, and which he describes in the following words:

"Not with the eyes of the body, but of the mind, I saw myself coming toward myself upon horseback, wearing a dress such as I had never worn. It was fish gray, with gold. As soon as I shook myself out of this dream, the figure was entirely gone."

An illusion, finally, is that form of sense deception in which an actual sensory stimulation is consciously perceived but in a falsified manner. If

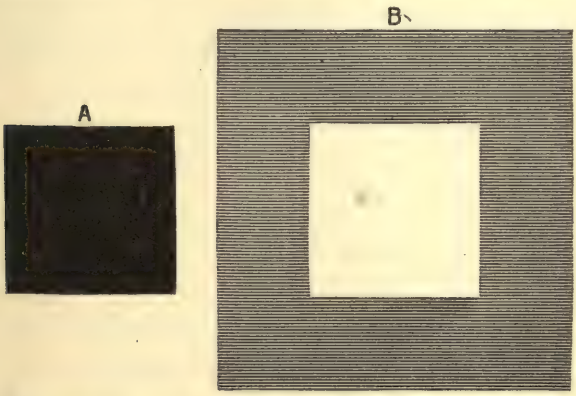
things are seen, heard, felt in a way different from that in which normal people see, hear, or feel them, we designate such conceptions as illusions. The rustling of the leaves, for instance, may be taken for a voice, a shadow for a human being, etc.



The parallel lines, A, B, C, D, and E, in consequence of the diagonal cross-lines, seem to converge or diverge.

The main difference between a hallucination and an illusion is that in the former an external object which might have produced a sensory impression does not exist, while in the case of an illusion such an object acts correctly on the sensory organs, but is falsely perceived. There exists a large number of illusions which because they are common to all of us may be termed physiologic. Thus, for instance, under certain conditions two lines of

equal length seem unequal, two parallel lines seem to converge or diverge, or, as before mentioned, of two equal-sized squares the one seems to be larger than the other, and a rod immersed in a basin of water appears to be broken. Similarly, a small



Of the two equal squares, A and B, the black upon a white background appears to be smaller than the white upon the shaded background.

sphere, like a pea, rolled between the crossed index and middle fingers, seems to be two spheres.

Practically, a sharp differentiation between hallucinations and illusions is not feasible. So far as the senses of taste, smell, and touch are concerned, we cannot always determine whether an abnormal sensation—a fetid taste, for instance—is a hallucination or whether there exists an illusory misrepre-

sentation dependent on an actual perception, such as the pappy taste in a catarrhal condition of the digestive tract.

Aristotle's experiment.

A marble rolled between the crossed index and middle fingers gives the sensation of touching two spheres.

While we are able to assume as a rule that hallucinations and illusions, in so far as they are not dependent on diseases or destruction of the peripheral sensory organs, have their origin in the brain and that, more specifically, disorders of circulation in certain regions of the brain cortex are involved in their production, there can be no doubt that people of good mental health may be sub-

ject to sense deception. In such cases, however, hallucinations are much less frequent than illusions.

Here again we must lay stress on the fact that sensory deceptions in persons of healthy mentality are of little significance inasmuch as they are susceptible of correction, while in the mentally disordered they usually obtain an irresistible influence over not only all the thought processes but also the emotional tones and the impulses of the will. If such sensory deceptions remain uncorrected in the healthy person, if they obtain a firm hold and, together with the dependent conclusions and opinions, acquire permanent dominance of the mind, they may become dangerous to the victim.

The possibility of mental health even in persons of defective sensory perceptions is eloquently proved by the fact that many people congenitally blind or deaf can develop in an entirely normal manner, although they have no idea of color or of tones, and by the fact that Helen Keller, despite her lack of both those senses, which bring about the chief connection with the outer world, went successfully through a well-planned academic course and now occupies herself ably in literature. Such development of defective sensory perception,

of course, can only be understood by the presumption that the defects can be corrected.

How great a power sense deception and false concepts may exert not only on the mental activities but also on the physiological processes of entirely healthy persons has been demonstrated by Bechterew in the following drastic example:

In Copenhagen, in the year 1750, a criminal condemned to death was turned over to the physicians as an object of study. The unfortunate was fastened to a table by means of heavy leather straps and blindfolded. He was then informed that an artery of his neck was to be opened and that his blood would be allowed to drain until not a drop remained. An insignificant prick of the needle was inflicted, a suction-tube was placed next to the man's head, and a stream of water flowing across his neck was allowed to splash into a vessel standing on the floor. The criminal, firmly convinced he was listening to the dripping of his own blood, died as a direct result of the illusion.

An example of a similar kind, reported by Rochas, is this:

A number of students seized a school employee who had displeased them, held a mock trial and

condemned him to death. A block and an axe were brought forth and the prisoner was informed that within three minutes the death sentence would be executed. His neck was bared, his eyes were bandaged, and he was made to kneel. Then, with a wet napkin, a blow was given him on the neck. The students laughingly declared the death sentence fulfilled, but to their great astonishment the man did not move. By great effort he was revived, but he had to be placed in an asylum as incurably insane.

Those, of course, are individual and extreme examples. In a normal brain the imagination alone will not always be able to produce marked disorder; fear and the expectancy of immediate death will not always be able to paralyze vitally important functions. That the majority of criminals condemned to death are yet fully alive at the moment of execution and that their life is extinguished only by the act of execution, proves the expectation of death is not sufficient to cause cessation of the action of the heart or of the movements of respiration.

The two examples given above, however, do show how effective may be the power of imagination

in producing severe disorder in bodily processes as well as in the mental sphere. Later we will demonstrate that this same power of imagination may also be of beneficial influence and that in psychotherapy it has already been developed into an efficacious curative factor.

In the same connection we must mention "psychic infection" and functional nervous diseases, neuroses. By psychic infection we understand the aggregate of all psychic influences which force mental action into false channels. "Functional" nervous diseases are those disorders of sensation and motion in which no organic changes are discoverable and which, therefore, like hysterical paralyses, may be dependent on imagination alone.

That the term "neuroses" or "functional" nervous disease refers to disorders which have as a basis no structural changes and which, therefore, are due to mental causes, must be kept constantly in mind. Through the progressive improvement in anatomical methods of examination, the field of neuroses has steadily become more and more limited. In recent years the refinements of microscopical technique especially have given us a clearer insight into the more delicate structure of the ner-

vous system and have enabled us to recognize as deviations from the normal many tissue formations, the pathological character of which we had not been able to perceive by the older methods. Hence it might be assumed actual neuroses do not exist and that, simply because we are unable to demonstrate the existence of organic changes which perhaps form the basis of those disorders, we necessarily designate them as functional or psychically induced. In another century, possibly, science will have made such progress that the final enigma concerning neuroses will have been solved. For it must be enigmatical that such serious disorder as may be observed in hysteria, neurasthenia, and other troubles should be possible without corresponding change in the gross or more delicate conformation of the organs of the body and of their nervous elements, while everywhere else in pathology the law holds good that disease is a manifestation of life under abnormal conditions.

This question might be answered by the contention that the psychic cure of such disorders in itself furnishes the proof of their psychic origin. Obersteiner, who has given us an excellent dissertation on the most important differences between

functional and organic nervous diseases, very justly states it must be impossible to assume that a severe hysterical paralysis cured by assertion alone could be dependent on anatomical disorder. How could such an anatomical change be set aside by simply arousing a belief in a cure, even if the belief is supported by the "water of Lourdes" or any other similar curative factor? Hence there can now be no question of anatomical change in such cases. Neuroses are and must remain psychic in their origin. Functional nervous disorders are caused essentially by the erroneous idea that specific functions cannot be carried out. It is just this false idea which produces the abnormal condition that limits or entirely prevents the exercise of the function. Therein, therefore, lies the explanation for the apparent contradiction between functional disorders with and without organic changes, for in both cases the expressions of disease are manifestations of life under abnormal conditions.

With Obersteiner, we may summarize as follows the results of previous investigation regarding functional disorders:

According to our present knowledge, many diseases which formerly, in the absence of any ana-

tomical basis of explanation, were classed among the functional disorders, are, as a matter of fact, organically caused; furthermore, the field of neuroses becomes still more restricted through the elimination of those abnormal manifestations of life which have their causes in toxic conditions, disorders of nutrition, hyperæmia, and anæmia. Even if we fail to prove clearly the existence of structural changes in these conditions, the presence of a material basis for their occurrence is sufficient reason in itself for separating them from the category of functional disorders. But even with the exclusion of those cases, there still remain numerous neuroses which present many evidences of disease which frequently are very severe and which have purely psychic causes. If, for instance, a person with a weak nervous system has a fit because he has seen another person in a convulsion, no special proof is required to show that his convulsions were not dependent on organic disorder and that an organic nervous disease never can be incited by pure imitation. The same test will apply to hysterical paralysis, to the sensation of a ball sticking in the throat, and to other manifestations of hysteria. In the same category must also be classed

all neurasthenic and allied states, obsessions, the neuroses without any anatomical lesion of the central nervous system which are caused by accidental injury, and also the functional psychoses, those expressions of diseased mental life which have no foundation in organic changes of the brain. Not only do we know that psychic symptoms are the dominating ones in the conditions we have mentioned, but we also know they are psychically caused and, on the other hand, can be psychically influenced. Obersteiner, therefore, arrives at the conclusion that, while the mere lack of demonstrable changes in the nervous system does not justify classing a form of nervous disease among the functional ones, differentiating between functional disease and functional symptoms would materially conduce to the better understanding of this difficult subject. A picture of disease may be made up of organic and functional symptoms. It may even be asserted that the majority of apparently pure organic nervous diseases also possess a functional factor, the latter then being capable of correction while the organic symptoms are not.

The important and difficult distinction between functional disorder and functional symptoms should

now be clear. The first expression denotes a total or partial inability to carry out a function, without it being possible to detect the existence, in the particular organ, of any changes which might be the cause of this disability.

Functional symptoms, on the other hand, are morbid alterations of function resulting from pathologic anatomic processes. In the one case as well as the other the outward picture of disease may be one and the same. If, for instance, a certain movement of a limb cannot be carried out, this inability may be due to an interruption in the nerve conduction or dependent upon a structural disease of the muscle, and may have been caused by mechanical injury, by infection, toxic processes, etc. On the other hand, none of these causes may obtain, in which case the disorder of function can have been produced only by psychic means. If this is so, then a cure by psychic means, by the arousal of the relative opposing idea, must be possible. At the same time, of course, it is not impossible that the functional symptoms, due to anatomical disorder, which are simultaneously present, but which take their origin in some other organ or part of the body, may be, possibly only

indirectly, ameliorated through this psychic treatment.

It must be looked upon as an assured result of anatomico-physiological brain investigation that the normal course of mental processes is associated, up to a certain degree, with the integrity of the brain cortex. It is entirely impossible, however, to localize the individual activities of mental life in certain regions of the brain cortex. Here we are dealing with conditions which lie beyond the scope of the anatomist and the microscopist and which, therefore, must be conceived as functional. While recognizing all the truth there may be in the basic idea of Gall's teaching concerning the different functions of individual regions of the brain cortex, we must nevertheless, as Obersteiner emphasizes, not lose sight of the fact, so eminently important for the understanding of functional symptoms, that it is essentially the activities of motion and sensation which have been definitely localized in single parts of the cortex; but we have not yet succeeded in grouping the various phases of distinctly mental life in a similar manner upon the surface of the brain, or even in placing them positively in any circumscribed portion of the cortex.

The endeavor to find an ample anatomical basis for functional disorders becomes futile just as soon as we no longer seek functional diseases but look for functional symptoms. All pure functional nervous symptoms or groups of symptoms have common characteristics which justify placing them in the field of psychic symptoms, even when their outward manifestations become material, as they often do. It is only on that basis that we can explain their cure by psychic influence. Moreover, even where the picture of disease is composed of organic and functional (psychically caused) symptoms, the amelioration obtained by suggestive influence can be explained only by the assumption of the existence of a functional factor in most apparently pure organic nervous diseases.

As a matter of fact, there is no single nervous symptom which could not occur in either functional or organic disorder. Paralysis and spasms, anæsthesia and hyperæsthesia, are found as symptoms of the one as well as the other. It may be maintained in a general way that symptoms of disease in fields not under the influence of the mind or of the will are evidences of anatomical lesion of the nervous system, while disorders of the psychic

sphere are more rarely organically caused, or frequently are to be looked upon as functional concomitants of an existing nervous disease. As a classical example in proof of this distinction, we may take the difference which exists between a hysterical hemiplegia and one dependent on hemorrhage into the brain. To the layman the clinical picture of disease is apparently the same. Not so to the physician, for in the one case he is able to efface the symptom by means of psychic treatment, and in the other case he cannot. A similar condition of affairs obtains in those disorders of sensation and of other kinds, already mentioned, which, when viewed cursorily, may represent symptoms either of anatomical lesion or mere functional disorder. In all those cases careful examination and precise knowledge alone can guard against mistakes in diagnosis and treatment.

II. SUGGESTION AS A PSYCHIC FORCE

A. Possibility and Nature of Suggestion

THE outer world exists for each of us as each of us conceives it. Each thing in our environment always exerts the same excitation on our brains. But our consciousness does not always react to any single excitation in the same manner. The world about us, broadly speaking, does not change, while the concepts which we form in regard to it may easily change. In that susceptibility of the concepts to change lies the possibility of suggestion, of psychic influence.

Bechterew defines suggestion as a special kind of influence exerted by one individual upon another, with or without the intent of the former, and without the previous knowledge or positive concurrence of the latter. The force of suggestion is based on the arousal of a conviction, unopposed by any contrary idea, that a certain proceeding will take place. In so far it involves not so much a logical conviction founded upon reason as that

credulity which springs from the emotions, which frequently is obtuse to all processes of reasoning, and which sways a person without his being able to account to himself for his notions.

The extremely characteristic expression "psychic infection" has been selected to designate this process.

A physical infection, as is well known, takes place through the interaction of three factors. First, there must be present germs which carry the infection; second, these germs must find an entry into the organism; third, conditions favorable for the development of the germ must exist in the organism.

It is in a similar manner that the processes of psychic infection take their course. We may look upon the carriers of physical infection as being represented, in psychic infection, by all those ideas which are able, whether by force of example, of speech, or of printed word, to incite the imitative impulse in the brains of persons who are receptive —that is, weak-willed.

True, the word "infection" connotes something morbid, an impression which should not necessarily be attached to suggestion.

According to Forel, suggestion represents an inroad upon the association of ideas—"it dissociates that which has been associated and associates that which has not been associated." Those chains of thought which have fixed themselves in our brains as a result of the education or the experience of years, and on which our entire intellectual activity is based, may therefore be disrupted, or new chains may be constructed, by an outside invasion. That is to say, ideas which hitherto have been foreign to one's conceptional life may be aroused by means of suggestion.

But not every suggestive influence attains its purpose; many suggestions founder on the opposition of persons of strong will. In order that a suggested idea may exert its action, not only is it necessary that it be introduced into the brain, but also that it be adopted by the brain. In contradistinction to persuasion, the methods of which usually consist in logical exposition and argumentative proofs, suggestion acts by means of a direct transplantation of mental states, ideas, emotions, and sensations; it is heedless of proof and effective without the aid of logic, swaying solely by means of the force and vehemence of words, by

means of gestures and other mimic movements. While persuasion attains its ends chiefly in strong and healthy minds, the successes of suggestion are most marked where a lower degree of mental development is encountered—in children and people of the lower classes, for instance.

Not all persons, therefore, are equally adapted for the acceptance of suggestions. Suggestibility is dependent on the strength of will, the character, the impressionability; it varies according to age, temperament, sex, education, habit, and culture. The suggested idea, says Engelen, causes other buds to blossom in the brain of an impulsive young woman with lively imaginative powers than in the brain of an old, sober, coolly calculating and keenly critical scientist; other flowers in the brains of people with dominating emotions than in the brains of sceptics.

Over a person of strength of will, one to whom the suggested idea is discordant or even repugnant, the suggestion will prove powerless, while persons of yielding tendencies generally will accept it easily and carry it out.

Furthermore, the immediate mental state of the individual to be influenced must be considered.

Whatever benumbs the powers of judgment and resistance, whether it be fatigue, torpor due to alcoholic or other narcotic depression, fear, or passionate excitement, will enhance the suggestibility. Suggestion produced by taking a person unawares and leaving him no time for reflection acts in the same manner. Suggestibility is also increased under certain pathological conditions—for instance, in hysteria. In fact, suggestion finds all individuals of irresolute character and feeble will-power receptive.

As the result of many experiments, it has been shown that deliberate psychic inoculation is most easily effected during a special state of consciousness, that known as hypnosis. As a matter of fact, the acceptance of the suggested idea during hypnosis may take place with such force that the sensory perceptions and the entire contents of consciousness—even the personality itself—become changed. Through illusory confounding of objects by the hypnotized person, a walking-stick may be transformed suggestively into a dangerous snake; a handkerchief into a violet; a small child into a rabbit. Salt water may be swallowed by him as a rare wine; asafœtida may have for him

the odor of a rose. By the production of hallucinations we can conjure up in such a dissociated personality the picture of a wondrous garden which does not exist and have him gather flowers from it for a bouquet; or we may lead him in a row-boat over a tearing stream and have him live through all the terrors of a shipwreck.

"Every rational conjecture is cut off and consequently the maddest of confabulations are possible," says Engelen.

To the hypnotized person's eyes the moon may be made to fall on one of the spectators and set him aflame; on command the frightened subject will dip air, instead of water, from a hat and laboriously attempt to extinguish the fire. The conscious concepts may be interrupted to such an extent that the subject will forget his name, age, and home, and apparently become a new personality. Krafft-Ebing, in fact, reports a very interesting case of the reconstruction of a previous personality.

To a woman, Ilma Szandor, thirty-three years of age, showing no evidence whatever of hysteria, was suggested the seventh year of her own life, and then she was confronted by her mother.

When asked, "Who is that?" she ejaculated, "My mother, but she is so changed in appearance!" Then she burst into childish tears. This woman, therefore, was dominated by the false belief that she was seven years of age; she had in mind the appearance of her mother in that period of her own life, and she was alarmed by the change which twenty-six years had produced in her mother's looks. Krafft-Ebing says it will never be possible, even in pathological fields, to produce more convincing proof than this of the reconstructed personality.

On the other hand, the existence of a complete cleavage of consciousness in certain individuals may be demonstrated by means of hypnosis. In such cases the subject, when hypnotized, knows nothing of what he has done in the waking state; when in the latter condition, he has no recollection of the hypnotic happenings. Such an instance of cleft or double personality is cited by Bernheim. The subject is a young man, twenty-five years of age, whose complete metamorphosis can be accomplished by a mere glance. As a rule he is earnest, mild, quiet, and timid. Suddenly he becomes hilarious, reckless, intrepid. A worm is shown to

him and he seizes and examines it with interest. A touch on the forehead brings him back to the normal state. He sees the worm, throws it from him, and turns away in disgust. "But you had the worm in your hand just a moment ago," he is told. "Oh, but that is a joke," he replies. "I have such a loathing for it that I would not touch it for all the money in the world." He has forgotten everything which happened when he was under the spell. Another glance suffices to restore that condition, and with no prompting whatever he again seizes the worm.

Besides the sudden revivals of memory impressions which have already been mentioned, we encounter in normal life other occurrences which remind us of states of double consciousness. In this category belong those causeless, recurrent emotional changes of certain people. Those changes may be so marked as to represent a complete temporary transformation of the moral self, so that, according to Bernheim, the most timid person will, at command, pick up a revolver, in order in cold blood to shoot a harmless observer completely strange to him, or in order to commit the most intricate thefts. In the higher degrees of such

alteration of consciousness, of course, a pathological disorder of emotional life is recognizable.

Such remarkable occurrences as those instanced above were attributed at first to mystification of the observers, or even to direct trickery, but they must be explained for the greater part in the same manner as hysterical paralyses or other functional disorders in which the great power of the imagination discloses itself. In the normal state a deception such as occurs in hypnosis will hardly be possible; it will be prevented by the control of the sensory organs combined with active attention and by the proper functioning of the mentality.

If, for instance, we say to a person in the waking state, "Do you see this dog?" the expectation of seeing the dog will be aroused by the credulity natural to every one. The attention becomes concentrated on the fixed memory picture of a dog, and almost at the same instant is directed toward the sensory organs which immediately develop their controlling and corrective activity. The person sees no dog, the brain impression of the dog is not projected outwardly, but is wiped out, and the recognition of the deception ensues. In hypnosis, where the active attention is distracted from

the sensory organs and control, therefore, is lacking, all is different. The picture of the dog actually is projected outwardly; a visual hallucination arises. Such sensory deceptions, accepted during hypnosis, often produce in their turn a very intense reflex action upon the organism, entirely analogous to that which occurs when the ideas are produced by actual sensory perceptions. Thus, if a cold bath be suggested to a hypnotized person, the adoption of the suggestion is demonstrated not only by the typical facial expression which is an outer reflection of the inner shudder, but also by the goose-skin which is produced thereby.

Furthermore, tears may be drawn from the eyes of a hypnotized subject simply by the suggestion of physical or mental pain. We see from this that those disorders which are based on imagination alone, and which, according to Rosenbach, may be designated ideational diseases, are really perceived as actual illness.

This fact is of the greatest importance in treatment. Patients suffering from such "imaginary" diseases will never be cured simply by passing over their complaints with a smile or a shrug of the shoulder, or by attempting to talk them out of

the belief that they are ill. On the contrary, they must be treated as the really sick persons that they are, requiring sympathy and medical attention just like other persons who are ill. We must always keep before us the fact that the personal consciousness, the "ego," controls the adoption of external impressions, modifies the course of ideas, and acts determinatively on our actions. Only thus can it be explained that pains arise or disappear through suggestion alone, that persons or things may be falsely recognized, that objects which do not exist may be assumed to be actually present, that disorders of motion may be produced or removed, that the contents of consciousness may be altered, even to the extent of the effacement of the entire personality, etc.

In this connection it is of interest to consider in greater detail the special relationships between suggestion and hysteria. In his contribution to psychotherapeutics, which he entitles "The Pathological Principles and Fields of Psychotherapy," Prince takes the ground that hysteria is based on a dissociation of personality. When the memory seems for long periods of time to have disappeared, when the feeling predominates that certain move-

ments cannot be executed, when sensation to pain apparently no longer exists in certain parts of the body, or when the sufferer from hysteria feels as though a ball were sticking in his throat, the condition can be accounted for only as the result of dissociation. Certain ideas have become disconnected from the contents of consciousness. They have entered the subconscious, and, therefore, do not respond to the corresponding stimuli.

Prince very justly emphasizes the fact that dissociation, in itself, is a function of the normal brain mechanism, just as is association, and exists for the purpose of facilitating the adaptation of the individual to the constant change in his environment. A pathological impress is created only through that excess of dissociation which renders orderly association impossible and which abolishes the unity of the personality. That any such excess can be a question only of purely functional disorder is proven by the fact that hysterical paralyses, amnesia, anæsthesia, etc., may be produced or removed by means of suggestion in the waking as well as in the hypnotic state.

It must not be overlooked that the potency of a suggestion depends finally on the personality of

the suggester. Above all he must be enveloped, in the eyes of the person to be influenced, by a halo of authority.

There are persons who captivate our admiration, whom we face with timidity, enthusiasm, or fear, who exert over us a mysterious power, and whom we blindly believe without requiring demonstrative proof. Such fascinating personalities sometimes exert an influence over others merely by force of their dramatic talent, without themselves being convinced of the truth of their words, and they are born suggesters. Others who honestly believe in the truth of their own ideas possess no powers of suggestion at all, because they are unable to impress any one with their beliefs, in consequence perhaps of their insignificant appearance or of their timidity.

It has previously been said that suggestion has no power over strong characters. Practically, this fact is almost a negligible quantity, for individuals with unalterable ideas are exceedingly uncommon. No person is completely unreceptive of the suggestive influence which lurks about him, infiltrates his thoughts, emotions, and will, and insinuates itself into his subconsciousness.

We must remember, furthermore, how great is the number of those moral cripples who, as Bechterew says, are kept from profligacy, theft, and other crimes only through fear of legal punishment. To dispose such individuals to the execution of crimes which they would otherwise have avoided, would it not be sufficient to suggest to them exemption from punishment, suggestively to allay their fear of prosecution, and at the same time to present to their imaginations certain advantageous phases of the criminal acts? This question involves the fact that, where criminal acts are committed under the force of suggestion, the mere fact that the suggested idea has been adopted is sufficient proof of the previous existence of a criminal tendency. Legal responsibility for such acts, therefore, is by no means nullified, even if suggestion cleared the way for them. Mitigating circumstances, however, may well be pleaded and recognized—the same mitigation which the law usually accords to one weak enough to allow himself to be tempted by a stronger personality.

The character which a person receives as a life estate gives to his manner of living a certain physiognomy, impresses its seal upon it, and constitutes

the hidden spring which regulates his conduct and action. The stronger this spring the more is the individual governed by it, rather than by external influences, just as a rifle ball is deflected the less easily from its course the greater the force which drives it from the barrel.

Unfortunately the natures which triumph over every temptation and avoid every misstep are extremely rare. There are people who seem to be immune from perversion, but for the majority life is a series of compromises, because they lack the power to adapt the environment to themselves, and must therefore adapt themselves to the environment. In this throng of feeble-willed persons, who unopposingly submit to external influences and, through cowardice, yield to foreign power, who allow themselves to be swayed by other minds, are to be found all varieties of natures—from those good but timid ones which accept every idea forced upon them with assurance to those who, from inconsistency and irritability, are constantly changing their opinions.

This character weakness, whether it be more or less abject, or more or less radical, always has the result of making its possessor impressionable

and receptive of suggestions from the surrounding world. If such persons are placed among favorable surroundings, under the influence of good suggestions, they will become honorable—at any rate, before the law. If they are brought into unfavorable surroundings, where they will be subject to noxious suggestions, they will easily fall into devious paths. We know that criminal tendencies frequently are kept in restraint if the opportunity for criminal acts is wanting, or if the individual is not exposed to any great temptation.

Lombroso tells of a man whom he knew personally as occupying a highly respected position, and who, in a moment of confidence, confessed to the scientist: "If I had not been born rich, I would have stolen."

Weakness of character and of will, as it is encountered particularly in hysterics, produces a high degree of receptivity for suggestive influence, in a good as well as in a bad sense. The surrounding conditions exert their influence in allowing the manner of living of these unstable individuals to be swerved, now in one direction, now in another.

How often, for example, do we hear that young people, through reading criminal novels and other

lurid writings, through seeing obscene pictures, through lascivious stage productions, through improper moving pictures, received the first impetus to a life which finally brought them into conflict with the criminal law! Quite as many facts, on the other hand, may be adduced to show that literature and art, words and example, may also exert an ennobling and strengthening influence upon weak characters.

What has thus far been said shows, at any rate, that suggestions, whether they emanate from a novelist or an actor, from parents or educators, from friends or from people of whom one stands in awe, whether they infiltrate our perceptions by direct contact or by pictures or printed matter, whether they influence us perniciously as a "psychic infection," or whether they exert their beneficial effect in the form of a psychic curative remedy, do play an extraordinarily large rôle in the life of every person.

B. Scope of Suggestion

We have seen how great a power ideas, with their accompanying tones of emotion, may wield not only over our thoughts and actions, but also

over the functions of our bodily organs. The totality of our mental activity depends on nothing but ideas. Even when an idea is not the result of an actual stimulus, when it is dependent on simple imagination or is produced through sense deception, it gives rise to the sensations which specifically go with it when there is an actual stimulus. A person who believes he has been pricked by a pin feels the sting and makes a movement of protection. One who believes his food to have been prepared in a disgusting way experiences repugnance and may vomit solely in consequence of the idea. In a series of tests of the electrical excitability of various persons, Dubois used a non-active unconnected battery, and yet he found that most of his subjects, thoroughly believing the electric current had been applied, were able to give accurate descriptions of sensations which might have been expected only from an active battery and which ranged from a slight tingling or burning up to unbearable pain.

Man feels what he conceives as soon as he is entirely convinced of the correctness of his conception. Simple imagination, the mere expectation that a certain thing will happen, suffices in most

instances to alter bodily functions, to produce or allay sensations of pain, or to bring about other conditions conforming to those which would result from a real experience of the thing imagined.

From that it will be appreciated that the possibilities of suggestive influences are exceedingly numerous. Especially for pedagogy do those possibilities furnish a responsive field of action, and therefore they should be of great interest to parents, teachers, and educators. We hope at a future time to take up a consideration of suggestion as a factor in instruction.

Suggestive possibilities, however, have distinct limitations, set by the laws of nature. We can produce false concepts and sensory deceptions, with their accompanying sensations, or remove such concepts by awakening contrary conceptions, but we cannot bring about any organic change by means of suggestion. Kant, in the work previously alluded to, speaks advisedly of "disordered feelings" which can be overcome by the mere exercise of the will, rather than of disease. An example which proves the rule is that of a celebrated university professor who, although suffering from an incurable and extraordinarily painful disease, was able to lecture

regularly up to within a short period before his death. The distraction which this occupation in his special field afforded to him and the intense interest he took in his youthful auditors enabled him to forget his pain as soon as he was on duty. But the disease itself followed its inevitable course.

In the process of recovery from disease the emotional state of the patient plays a not unimportant rôle. Depressed feelings and hopelessness militate against the recuperative process, buoyant fortitude and a cheerful mood foster it. To that extent the course of disease certainly may be influenced by the use of suggestion.

Bodily functions may be affected by means of suggestion, though organic changes cannot be brought about. A patient may be made to believe, on receiving a subcutaneous injection of water, that there has been an injection of morphine, and the conviction that the opiate will have its natural effect may lead him soon to go to sleep. But it is not possible for imagination to reverse the natural effect when a real drug is used. In a constipated person the ailment cannot be relieved by the administration of tincture of opium, with the accompanying suggestion that an aperient is being given,

nor can diarrhœa be checked by giving jalap under the name of a constipating dose. Similar examples could be given without stint. Pilocarpine might be administered to a tuberculous patient troubled with night sweats, atropine to a sufferer from chills, and so forth, and each administration accompanied by a suggestion contrary to the physiological and therapeutical attributes of the specific remedy, but the expectation that our entire drug treatment might be turned topsy turvy by such means would in all cases meet with disappointment. Notwithstanding all contrary suggestions, these medicaments would act in accordance with the laws of chemical affinity.

The fact that no incongruous action of medicines nor organic change of the tissues can be produced by imagination alone is of fundamental significance as regards suggestion in general, and as regards its therapeutic application in particular. One lesson that it gives is that the action of drugs may be enhanced by means of suggestion, though it cannot be reversed.

By arousing in the patient the positive expectation that the action peculiar to the remedy will set in, suggestion actually does promote indirectly the cure of bodily diseases and the removal of or-

ganic disorder. The connection of this psychic curative factor with physical processes of disease may be recognized, therefore, if we keep in mind that the regulation of bodily functions cannot but influence the retrogression of organic changes, and that the removal of functional disorders, particularly, constitutes one of the chief fields for treatment by suggestion; and if at the same time we recall not only that bodily states act on the state of mind sometimes exhilaratingly, sometimes depressively, but also that, conversely, the mental state influences the physical processes.

We must never lose sight of the fact, however, that psychic influence alone is not capable of producing anatomical changes. No kind of suggestion can produce a sarcoma or other new formation, nor can it cause the removal of an existing one. Tumors do disappear without surgical intervention, though very rarely, and certain tumors clinically diagnosed to be cancerous have disappeared with or without the use of drugs. Just what led to the nutritional change which caused the atrophy of such tumors cannot be stated, but we have no reason to suppose that suggestion alone was a material factor in their disappearance.

Krafft-Ebing and Forel have instituted detailed

experiments to ascertain whether there is a possibility of causing organic change by suggestion. They are said to have succeeded, by the power of suggestion alone, in producing blisters on the skin, as well as burns and hemorrhages. Those effects were produced merely by laying a piece of paper on the skin. The blister appeared when the subject was informed that a mustard plaster was applied, the burns were produced by attributing to the paper the qualities of glowing metal, and the hemorrhages by attributing to it the qualities of the cupping-glass. Even assuming the deception in each case was a complete success and that the effect logically to be expected ensued, and ignoring the fact that Krafft-Ebing and Forel themselves admit these experiments rarely were successful and that, when they were successful, had to be most sceptically received, the result does not by any means overthrow the rule that organic changes cannot be produced by suggestion alone. In our opinion it is an ample explanation in these instances to say that it was a hyperæmia due to suggestion, and, therefore, a functional change in the circulation of the blood, which caused the hemorrhages and the alterations in the skin.

Incidentally it may be said that the so-called maternal impressions of pregnant women, the supposed causation of malformation of new-born children by alarming visual impressions received by the mothers during pregnancy, have been proven fictions. All in all, it is not going too far to assert that, according to the present status of science, the direct production of organic changes lies entirely beyond the possible effects of suggestion.

In considering the possibilities of suggestion, we must not overlook the question whether suggestion is capable of causing a person to perform any selected act. As is well known, the Nancy school, supported chiefly by Liébault and Bernheim, holds that the possibilities of suggestion are unlimited, and that, especially by means of the hypnotic state, every individual may be rendered completely devoid of any personal will. Against that contention we would mention the fact that, notwithstanding the astonishing effects of suggestion, the hypnotized subject is not a complete automaton, not a mechanical toy, in the hands of the hypnotizer.

No matter how powerful a suggestion may be, it is by no means received to the extent of extinguishing completely the subject's moral individuality, and

it cannot force a person to any act which he never would commit when completely conscious. A person thoroughly opposed to a certain idea cannot be compelled to act in accordance with that idea, even when it is forced on him by means of suggestion. The suggestion must be in accord with the innermost nature of the individual. For that reason not all suggestions are obeyed, but only those which the hypnotized person might in certain circumstances carry out on his own initiative at any moment.

According to Liébault, the hypnotized person follows the suggestion blindly—"he carries out what he has been enjoined to do with the fatality of a falling stone." It is quite true that certain facts seem to prove the truth of these words. Gilles de la Tourette, in his work on suggestion from the stand-point of medical jurisprudence, cites various interesting experiments in which the hypnotizer succeeded in effacing completely the independence of the individual, and in causing him to cast aside fundamental moral principles. At the command of the hypnotist, a girl known as righteous shoots at her mother; a young man of conduct above suspicion administers poison to his aunt; a lady kills

a physician who treated her unsuccessfully; another poisons a person entirely strange to her.

Even admitting that such cases, in which the hypnotized person accepts suggestions thoroughly contrary to his moral feelings, have occurred, we must agree with de la Tourette and the physicians of the Salpétrière that such instances not only are exceedingly infrequent, but that in each of them it is only with the greatest difficulty that the will of the hypnotized person can be obliterated. He yields only after opposition, and frequently there ensues a hysterical attack which proves how difficult it was for him to obey. That attack is regarded by de la Tourette as a retarded revolt of the organism against a deed which filled it with horror.

As is shown by his opposition to a suggestion disagreeable to him, the hypnotized person always remains an individual with a will of his own. His surrender under pressure proves nothing more than the existence of individual frailty; by no means does it prove that suggestion is omnipotent. The normal "I" always exists alongside the abnormal "I" created by the hypnotist. This abnormal "I" can be led to do something deeply repugnant to

the normal "I," but only under conditions which might be compared to those which are present in inebriety.

Suggestion, however, may weaken the will to such an extent that it can no longer be determined whether the will still exists. During hypnosis, things take place under the influence of the hypnotist's will which, for other reasons, take place in dreams, sleep-walking, or intoxication. The person in any of the three latter states does things which he would not do when in a normal condition. But his "I," much as it may be pathologically altered, nevertheless is constantly present; it is modified, but not effaced. It is easier to induce any one to commit acts ordinarily repugnant to him when he is in a state of hypnosis than when he is in any other condition, but even in hypnosis he will always manifest his proper nature, just as in sleep or in inebriety. It may be said, therefore, that under the influence of suggestion a person will show against which acts his innermost nature revolts. Consequently any crime willingly committed while in a state of hypnosis will always be caused partly, perhaps only to a minimal extent, by the organic disposition of the individual, for if this organic

disposition were not present, the individual would have withstood the suggestion.

Just as alcohol, in proportion to the duration and the strength of its influence, will paralyze or diminish the moral control which we possess as a result of inheritance or training, and which prevents us from following criminal impulses, so it may be said in relation to suggestion that, during hypnosis, the transition from an idea to an act will be the more prompt the fewer the obstacles and the inhibitory feelings which must be overcome to permit the suggested idea to rule alone in the narcotized consciousness. Let us not forget, however, that even in the deepest hypnosis a person cannot be driven to the commission of deeds which he would not have committed entirely independently of suggestion as soon as he had lost his self-control.

The alleged power of Hindoo fakirs to place themselves in a condition of apparent death has been mentioned by authors of note as a striking example of the scope of suggestion.

According to N. C. Paul, cited by Bunge, "fakir" is an Arabic word which signifies "mendicant." The term has been applied to the Hindoo mendicants and jugglers—more particularly to the

juggler adherents of the Yoga philosophy, those who have adopted as their aim in life the Yoga, that mystic fusion with the deity and the complete abnegation of sensuality by dominance of the mind over the body. Fakirs, therefore, are more correctly called Yogis. Reliable evidences of their accomplishments are very sparse, notwithstanding the statements of spiritists and theosophists that demonstrations of the Yoga are frequent in India. It is said some of the Yogis, by means of prolonged castigation, put themselves into a sleep which bears the impress of asphyxiation, with apparent cessation of heart and respiratory action. The Yogi immures himself in a narrow subterranean cell in which the temperature is unchanging, takes very little nourishment, cuts through the band under the tongue, then draws out the tongue repeatedly until it becomes elongated so he is able to double it backward upon itself and thus cover the posterior openings of the nasal cavity and keep the air in his lungs from escaping. Sleep is then effected through auto-suggestion and the exclusion of all distracting sensory impressions, combined with fixation of the Yogi's own nose. The Yogi then is laid in a coffin, occasionally even buried, and,

after a day or even a few weeks, disinterred and revived.

The documents of Braid, who calls this process of apparent death "human hibernation," are of importance. His interest in these occurrences was aroused by communications concerning them which were made to him by Dr. John Cheyne, professor in Dublin, a recognized medical authority. Special interest attaches to Braid's report of such apparent death in a European. Colonel Townsend, an Englishman, possessed the power of voluntarily causing a cessation of his heart and respiratory action and of remaining in a state of apparent death for a period of half an hour. Dr. Cheyne and Dr. Baynard, who were witnesses of such an act, state that they were unable to perceive any pulse or heart beat nor any respiratory movement, and that a clean mirror held to Townsend's mouth did not become dimmed. The physicians feared Townsend was dead, but after half an hour the heart-beat slowly returned, respiration set in, and the body began to move.

Braid says that, in the face of such testimony, he was no longer able to disregard the statements concerning such occurrences among the fakirs, or

Yogis, and he made further written inquiries of reliable people in India. These reports of cases collected by Braid include some in which actual burial, with or without a coffin, had taken place. Such burials of apparently dead Yogis certainly must be very infrequent. Paul, who, by the way, according to Schmidt, was an anglicized native of India, by the name of Navina Candra Pala, and whose reports for this reason are not unbiassed, mentions in his treatise only three cases of such burial. He says the bodies were placed in a vault, which then was covered by two heavy flat stones five to six feet long, several inches thick, and wide enough to occlude the opening completely, and, Paul believes, some earth was thrown over the stones.
